An electrical discharge that is harmonic rich still qualifies as RF. That pulse electric discharge is going to create a pulse magnetic field. Guess what? A magnetic antenna (as a loop is often described) will pick up that field as readily as an electric antenna.

>The bandwidth is so narrow in the 40 meter band, only a few kHz.
>So there is a smaller chance of strong out
>of band signals.
>
>By the way, having to tune the loop every time when changing frequency is a
>mayor disadvantage of tuned magnetic loops. The MFJ loop can be tuned rather
>quickly and the larger bandwidth (lower Q) makes it easier to hear stations
>within several kHz
>from the tuned frequency.

These are operational characteristics of a tuned loop. Look at your own subject heading: Magnetic Loop - not the same thing.

In fact, the term Magnetic Loop is an invented term. RF is both magnetic and electric simultaneously. All antennas respond to both. Your tuned loop exhibits astronomically high electric potentials. Would you care to guess how high the potentials are for receive as compared to the field potential it experiences?

Let's put some fantastical numbers to this last question. A reception field of 1V/M will exhibit ______ V on the capacitive elements of a resonant tuned loop with a Q of 1500.

>I don't think that it's just a matter of height. But maybe you are right. I
>can't put up a full size verticale on my balcony to compare.
>
>A magnetic loop will work indoor and outdoor. Low on the ground and high in

>require counterpoise. When there is little space or other restrictions the
>loop is a nice alternative.

A 2 meter wide dipole occupies less space than a 2 meter wide loop.
Once the dipole is matched, performance will be identical.

>For transmitting a magnetic loop can be also interesting when there is no
>space for a full size antenna.

You could as easily say the same for a full size loop. Do you notice
any irony?

>One could also for example use the full size antenna for TX and the magnetic
>loop as an
>alternative for RX.

Why?

>To me the antenna start at the Antenna connector of the tranceiver.

Then a lot has been unsaid for a tuner to any dipole.

>>>> As for loop efficiency, you state:

>>
>Maybe you can ask the manufacturer and post his explanation here.

Actually, you need to do this yourself as these are all your choices.
This is your offered explanation and your offered testimony. In fact,
in this, a technical forum, there is every expectation that you could
reasonably perform these technical matters and respond with results.
Do you have an Ohmmeter? Are you proficient in its use?

If you cannot on your own, and without prompting, reconcile 3%
efficiency with a Q of 1500, then you shouldn't be offering technical
advice about Q or efficiency.

>>>For example the loop calculation software of G4FGQ.
>>
>> Give us the entry data and the formula.

>You can download the loop calculation software and enter the dimensions of
>the loop. I don't have information about the formula.

I have corresponded with G4FGQ the software designer for YEARS.
Consult the archives. I understand how it works. The question was
for you to write what YOU did, and not what someone else might do.

Hi Richard,

Thank you for the explanations. I have not had the intention to start a scientific discussion here on this subject. To me it is a hobby. With my homepage I just want to share some of my experience with magnetic loop antennas, just like many other radio amateurs do. And of course I am willing to reply to reactions from readers. But I will not further discuss about scientifically details.

Thank you.

Best Regards

73,

Norbert PA7NR

No.. the original article was talking about low power 802.11/802.16 systems (which radiate less than a watt).. At that power level, the fact that a suitably good linear amplifier is going to consume a fair amount of power (20% efficiency would be doing well) is insignificant next to the power consumed by the digital processing necessary to implement the cancellation algorithm.

No.. I would expect that this would actually work fairly well. The idea is to allow full duplex operation, rather than the current half duplex used in, e.g., 802.11b/g. That would double the throughput (if traffic on the network were symmetric).

If you want to run full duplex, you have to have some way to "see" the received signal in the face of a much larger transmit signal. Since you're transmitting, you've got a copy of the transmit signal, so it's really a matter of figuring out what the transfer function is from transmitter to (self)receiver. If the external environment were fixed, then one could probably do it with a coupler with adjustable gain and phase. However, as you point out, the environment isn't constant, so you need a way to adaptively adjust. You could do it with a single transmit and single receive antenna, but that puts a tough dynamic range requirement on the system. Say, -20dB coupling from Tx to Rx antenna, +30dBm on transmitter, -100dBm received signal.. you need 110dB instantaneous dynamic range.. that would need a 18-20 bit converter, which doesn't exist at a reasonable price in the 10-50 MHz sample rates needed.

The idea of using a pair of transmitters to reduce the dynamic range requirement on the receiver is clever. I would think you could get 40dB suppression without too much trouble, which gets your instantaneous dynamic range requirement down to 70dB, which is starting to be in range

(there are inexpensive fast 14 bit converters, for instance)

I agree with ka7niq. Open wire is the only way to go. I'm using a 135 foot dipole with open wire and it works great.

And no electrons at all. Nothing jump off and come back. Only
incompressible, massles electric and magnetic fluids.

But the electrons exist. All radiations are the electrons vibrations. All
waves are asymmetric. So must be the electrons transport, Hot body loss
electrons. The all is to measure.

Your loop is not magnetic. Look at Fig. 2:
http://www.antiquewireless.org/otb/lodge1102.htm

Radio wavesare are radiated from the nodes. In dipole the nodes are created
by reflected wave (waves in the opposite direction). In the loop the waves
travel in oppsite direction and create the nodes also.

Verticals work like the Kundt's tube. Dipoles like the two Kundt's tubes.
A loop is like a dipole where the reflected wave is replacesd by the on from
the second wire.

Hertz has the dipole and the loop:

well, you go ahead and measure it, and take a picture of the
asymmetric waves while you are at it... once you publish in a peer
reviewed journal i'll start talking to you again, this is getting
rather boring since you refuse to learn.

If there is no charged aether, where does the "quantized field in a
vacuum" come from? From Wikipedia: "In quantum field theory, the
Casimir effect and the Casimir-Polder force are physical forces
arising from a quantized field. The typical example is of two
uncharged metallic plates in a vacuum, ..."

i am referring to a theory from around 1880 that had a sea of
electrons as the aether for propagating electromagnetic waves.

It is from 1846: http://www.padrak.com/ine/FARADAY1.html
Faraday wrote:
"I suppose we may compare together the matter of the aether and ordinary
matter (as, for instance, the copper of the wire through which the
electricity is conducted), and consider them as alike in their essential
constitution; i.e. either as both composed of little nuclei, considered in
the abstract as matter, and of force or power associated with these nuclei."

Aether and a sea of electrons (as the rare plasma) is not the same.The other
scientists needs a mystery aether where a strain, stress and flows take
place. Faradays electrons vibrate.

sorry, 1846, even older than i thought... aether, sea of electrons,
rare plasma, none are necessary for electromagnetic waves.

<sorry, 1846, even older than i thought... aether, sea of electrons,
rare plasma, none are necessary for electromagnetic waves.

EM are a paper waves. Real radio waves need a medium.

my em waves are made out of energy not paper... while Einstein says
they are interchangeable my radio would have a hard time receiving
paper.

Change "sea of electrons" to "quantum soup" and the aether theory is
alive and well. Even photons need a structure through which to
propagate.

Actually the "P-static field" originates directly from electrons while the EM field originates from photons. What a closed loop does with those excess electrons is quite different from what a single-wire dipole does with them. All points on a well-designed loop system have a path to ground in addition to the signal path. That's not true for a single-wire dipole. From 1/2 of a dipole, the signal path is the only path. That's why undischarged dipole systems can arc during conditions of P-static while loops don't arc. Wouldn't you say that an absence of arcing is less noisy than the presence of arcing?

In a dipole, the reflections are naturally from the impedance
discontinuity at the open ends of the dipole. In a loop, the
reflections on the antenna are from the impedance discontinuity at the
feedpoint.

On the contrary, a quantum soup is indeed required.  If photons could
propagate without a structure, they could exit the universe but they,
like us, are trapped and confined to the universe.

Hello Richard,

I agree with you that several statements on Norbert's site will not hold when scientifically reviewed. However I think the way you respond will likely not result in better statements.

As the name of the newsgroup indicates; this is a radio amateur group and Norbert site starts with "Dutch amateur radio station". This may require another approach then you should use in a professional environment. If you prefer that, Edaboard.com (just an example) is a more suitable place.

Now the result is a professional reaction of Norbert:

> Thank you for the explanations. I have not had the intention to start a scientific discussion here on this subject. To me it is a hobby. With my homepage I just want to share some of my experience with magnetic loop antennas, just like many other radio amateurs do. And of course I am willing to reply to reactions from readers. But I will not further discuss about scientifically details.
>
> Thank you.
>
> Best Regards
>
> 73,
>
> Norbert PA7NR

Because of rain, I had to stop some activity so I took a pocket calculator, some of my own course material and a used envelope within reach.

A loop with diameter = 1.27m (4m perimeter), made from 20mm (diameter) copper has an inductance of about 3.4 uH (reactance of about 77 Ohm at 3.6 MHz).

Radiation resistance (no coupling with other objects) will be about 1 mOhm.

AC copper resistance due to skin effect will be about 30 mOhm (based on uniform current distribution over the circumference of the tubing).

Q factor should be in the range of 2500
Radiation efficiency will be about 3%
Directivity is 1.5
Voltage between ends (100W input): 6.3 kVp.

Current through loop about 82 Ap

A half wave dipole will have about 1kVp at each end (depends on conductor thickness).

Effective area of antenna will be about 23 sqm (in free space).

1Vrms incident plane wave field (2.65mW/sqm) will result in about 61mW output power (about 150Vp across the tuning capacitor).

You probably know that measuring a lower Q factor may result in less overall efficiency (coupling to dissipative objects) or higher overall efficiency (coupling to metallic conductors that reradiate).

With kind regards,

Wim

Waves need medium to propagate. Some scientists prefer mystery aether some
ordinary matter. Faraday and Ludwig Lorenz were sure that in space is enough
mater and no mystery aether. Now everybody know that in space is ISM (rare
plasma + dust). It is ordinary matter (electrons, ions and dust). But radio
waves will be always the aether waves. So we also can say that aether
consists of ordinary particles.

I do not understand. A loop can be made of wires without any discontinuity
at the feedpoint. Pulses send from supply must collide in the loop. The
nodes appear like in a dipole but without reflections. For what you need
reflections in a loop?

It depends upon how one defines "ordinary". The structure of free space has existed since the big bang but man has only recently discovered the structure and is still somewhat ignorant of its configuration and characteristics. There is some evidence that the structure of space in which ordinary non-dark matter and non-dark energy exists, is made up of dark matter and dark energy.

> I do not understand.

A loop, like a dipole, is a standing wave antenna with a characteristic impedance in the few hundred ohms, e.g. 600 ohms. The reflections on a standing wave antenna have to originate from an impedance discontinuity. The feedpoint impedance of a standing wave antenna is Zfp =3D (Vfor + Vref)/(Ifor + Iref) where phasor math is used. Let's assume that the feedpoint impedance is 100+j0 ohms and the antenna is being fed with Z0=3D100 ohm feedline. There are no reflections on the feedline which means a Z0-match to 100 ohms exists at the antenna feedpoint. Assume the characteristic impedance of the antenna wire over ground is 600 ohms. The 600 ohm to 100 ohm impedance discontinuity at the feedpoint creates a reflection coefficient of 0.7. That's where the reflections on the standing wave loop antenna are coming from. One reason the feedpoint of a resonant loop is higher than for a 1/2WL dipole is that the reflection coefficient for the loop is 0.7 while the reflection coefficient for a dipole is obviously 1.0 at the ends of the dipole.

The concept may be easier to understand using a rhombic example. A terminated rhombic is terminated in the characteristic impedance of the antenna wire above ground, e.g. 600 ohms, which eliminates reflections on the antenna and turns it into a traveling wave antenna where the feedpoint impedance of the antenna is equal to the characteristic impedance of the antenna over a wide frequency range, i.e. Zfp =3D Vfor/Ifor, independent of frequency.

Removing the termination turns the rhombic antenna into a standing wave antenna and the feedpoint impedance becomes Zfp =3D (Vfor + Vref)/(Ifor + Iref), i.e. the feedpoint impedance is frequency dependent like other standing wave antennas.

I built one of those about 20 years ago to be able to hit the local
repeaters, coverage was a little disappointing. going to a 5/8ths with
5/8ths radials made a noticeable difference and was nearly as easy to
fabricate. The base of it with radials still adorns my chimney.

Jimmie

Curious combination of conflicting sentiments, there. What is suitable, and how should we recognize it?

> Radiation resistance (no coupling with other objects) will be about 1 mOhm.

There are many source for computation, I chose one that closely agrees with several at hand. Perhaps I made an entry error, so I will take the opportunity to examine that possibility here:
Rr = 80 � pi� � (dl/lambda)�
80 � 9.87 � (2/80)�
790 � (0.025)�
790 � 0.0006
0.49 Ohm

Of course, the possibility of mis-entry remains, and cross checking is helpful given an in dependant validation. If I examine my text further it uses as an example a smaller loop at a lower frequency
dl = 1m
F = 1MHz
(lambda = 300)
resulting in
Rr = 0.0084 Ohm
which is roughly 10 times your computed radiation resistance for a larger loop at a smaller wavelength.

Now, having said that, and examining my text for further possibilities of error, I find that, yes, I made an error. My computation was based for an electric dipole, not a loop. Let us examine the Rr for a loop from the equation from the same source:
Rr = 320 � pi^6 � (r/Lambda)^4
320 � 961 � (1/80)^4
307,645 � 2.44^-8
0.0075 Ohm
This, too, is very different from your calculation, but certainly that error is eclipsed by my own first reckoning. However, what does this say about efficiency based upon the original design (but computed for another)?

However, I did first ask Norbert for the equation used and the parameters entered. Testing those results did not appear to be appealing in the face of contradicting testimonial. It should come as no surprise that many testimonials are tested here. Testimonials stand or fall in such tests, and those tests are retested (as has given rise to this and your response).

Curiously we entered into this with how the loop has superior qualities over the standard dipole, and then the same loop is cited as being very inefficient. How such contradictions are held within the space of a short thread is certainly a denial of engineering professionalism, but denial is not the standard of merit that is typically lauded in this forum. A hearty defense of wounded ego raises suspicion even further.

One consequence of that demurral brings us to a rather remarkable insight in comparing the radiation resistance of the electric dipole to the loop within the same spread of the loop (and in certainly a smaller volume of space). The electric dipole enjoys 60 times more radiation resistance that certainly impacts efficiency to the same degree. This, of course, presumes no further errors in computation or application.

As I said, how that finds its way into antenna system consideration still remains a mystery.

>No.. I would expect that this would actually work fairly well. The idea

Expectation is not explanation and recital of full duplex vs half duplex is a duplication of what has been already offered.

>If you want to run full duplex, you have to have some way to "see" the

And there is the nut of contention. Software will have to accommodate to variation in environment and throughput suffers. This is old stuff. The magic of computation still admits of cost galore. More money for poor transfer doesn't add any sparkle to market possibilities.

Wimpie is right, Richard.

Please go back to your laboratory and speak to someone who understands your dumb-ass dialect. Also, please don't discourage those who are trying to contribute their experiences here. Try to be positive for a change.

John

How much is "a little extra"?
Is that the cut length or length through the holes?
If not, length measured from where on the TNC connector?
Is the driven element the same length as the ground plane elements?
Hint: They're usually not the same length. For example:
<http://kj4pwp.com/projects/Ground_Plane.asp>

>> So we also can say that aether
> consists of ordinary particles.

>It depends upon how one defines "ordinary". The structure of free
space has existed since the big bang but man has only recently
discovered the structure and is still somewhat ignorant of its

configuration and characteristics. There is some evidence that the structure of space in which ordinary non-dark matter and non-dark energy exists, is made up of dark matter and dark energy.

I prefer this: "It seems to be a natural consequence of our points of view to assume that
the whole of space is filled with electrons and flying electric ions of all kinds. We have assumed that each stellar system in evolutions throws off electric corpuscles into space. It does not seem unreasonable therefore to think that the greater part of the material masses in the universe is found, not in the solar [sic] systems or nebulae, but in 'empty' space" (Birkeland 1913).
Thorndike (1930) noted that "it could scarcely have been believed that the enormous gaps between the stars are completely void. Terrestrial aurorae are not improbably excited by charged particles from the Sun emitted by the Sun. If the millions of other stars are also ejecting ions, as is undoubtedly true, no absolute vacuum can exist within the galaxy."

A loop antenna' is a radio antenna consisting of a loop of wire or other conductor with its ends connected to a two-wire transmission line. They have a radiation pattern similar to a dipole antenna"

>> I do not understand.

>A loop, like a dipole, is a standing wave antenna with a characteristic impedance in the few hundred ohms, e.g. 600 ohms. The reflections on a standing wave antenna have to originate from an impedance discontinuity. The feedpoint impedance of a standing wave antenna is Zfp = (Vfor + Vref)/(Ifor + Iref) where phasor math is used. Let's assume that the feedpoint impedance is 100+j0 ohms and the antenna is being fed with Z0=100 ohm feedline. There are no reflections on the feedline which means a Z0-match to 100 ohms exists at the antenna feedpoint. Assume the characteristic impedance of the antenna wire over ground is 600 ohms. The 600 ohm to 100 ohm impedance discontinuity at the feedpoint creates a reflection coefficient of 0.7. That's where the reflections on the standing wave loop antenna are coming from. One reason the feedpoint of a resonant loop is higher than for a 1/2WL dipole is that the reflection coefficient for the loop is 0.7 while the reflection coefficient for a dipole is obviously 1.0 at the ends of the dipole.

>The concept may be easier to understand using a rhombic example. A terminated rhombic is terminated in the characteristic impedance of the antenna wire above ground, e.g. 600 ohms, which eliminates reflections on the antenna and turns it into a traveling wave antenna where the feedpoint impedance of the antenna is equal to the characteristic impedance of the antenna over a wide frequency range, i.e. Zfp = Vfor/Ifor, independent of frequency.

>Removing the termination turns the rhombic antenna into a standing wave antenna and the feedpoint impedance becomes Zfp = (Vfor + Vref)/

(Ifor + Iref), i.e. the feedpoint impedance is frequency dependent
like other standing wave antennas.

See: http://paws.kettering.edu/~drussell/Phys302/09.html

"Electromagnetic pulse in a coaxial cable reflects from a short circuit with
the opposite polarity (upside down)"

A loop is like a short circuit. What do a Electromagnetic pulse in a loop?
It simply travel trough the loop and looks like the "reflected with the
opposite polarity ". Why am I wrong and D. Russell is right?

What you are missing is that the loop is an antenna, not a
transmission line. On a transmission line, the currents are
differential, i.e. 180 degrees out of phase and a short-circuit is
possible. At the antenna feedpoint the left differential current takes
a 90 degree turn to the left. The right differential current takes a
90 degree turn to the right. *That puts the antenna currents in
phase*, i.e. in common-mode, so a short circuit on an antenna 40 feet
in the air is not possible. The fields that are 180 degrees out of
phase no longer cancel because of the physical distance between them.

From the feedpoint of the antenna, there is no such thing as waves
launched in opposite directions on the wire *at the same time*. What
you are missing is there is no short-circuit half way around a loop
because there is no impedance discontinuity at that point. Forward
waves continue traveling forward and reflected waves continue to
travel backwards at that point because there is no impedance
discontinuity at that point. It takes an impedance discontinuity to
cause a reflection. Assuming a circular horizontal loop (for the sake
of conceptual simplicity) the only impedance discontinuity is at the
feedpoint.

Hello Richard,

Your formulas can be disputed:

When using (from http://www.ece.msstate.edu/~donohoe/ece4990notes5.pdf):

Rr_loop =3D 320*(pi)^4*A^2/lambda^4

for f =3D 3.6 MHz, Dloop =3D 1.27m (so A =3D 1.27 m^2),

Rr_loop =3D 0.001 mOhm.

This result agrees the number in my previous calculation (for the same situation).

From the same source, but for a dipole of 1.27m with large end-plates,

Rr_dipole =3D 80*(pi)^2*le^2/lambda^2 =3D 0.18
Rr_dipole =3D 0.045 Ohm (without large end-plates).

This is roughly a factor 45 or 180 more (for the dipole).

Maybe somebody can confirm the above calculations.

The actual efficiency depends on the required (space consuming) reactive component to cancel the capacitive (dipole) or inductive (loop) behavior.

The advantage of the loop (especially for reception) is that you need a variable capacitor instead of a variable loop, and matching / balun function can be made easily. He also mentioned the vertical radiation component (NVIS operation) together with the nulls in the horizontal plane.

Regarding claims, Norbert didn't make claims about the high efficiency. Please read his conclusion that starts with "despite the low efficiency of 3%=85.". His stated 3% reasonably agrees with my 3% (though you think that the calculation may be wrong). The claim with regards to performance comparable to a half wave or vertical antenna is for higher frequencies (where the loop's efficiency increases significantly).

Of course I have serious doubts about the conclusions regarding general noise cancelling properties, but the conclusions can be right for that special RF-environment. Whether they apply for another situation, can be food for the radio amateur experimenter (or professional?).

With kind regards,

Wim

I didn't mean Wimpie was right about his technical response. I meant he
was right about a part of his message which you cut:

"I agree with you that several statements on Norbert's site will not
hold when scientifically reviewed. However I think the way you
respond will likely not result in better statements."

"As the name of the newsgroup indicates; this is a radio amateur group
and Norbert site starts with "Dutch amateur radio station". This may
require another approach then you should use in a professional
environment. If you prefer that, Edaboard.com (just an example) is a
more suitable place."

Hello Richard,

you used r =3D 1m (as you have r in your formulas), that is D =3D 2m,
6.28m circumference.

I used D =3D 1.27m (4m perimeter), that is r =3D 0.635 m.
```

Quote from Norbert's site:
"When a magnetic loop antenna is used for 3.5 MHz with a perimeter of
4 meter (13.3 foot) , it has an efficiency of approximately 3%."

Maybe this helps you to explain the difference between your and my
result,

Wim

because the referenced patent is talking about a *system* not just an
antenna. So the *system* implementation is relevant..

Then I'll just have to put the "point" back in

<Quote Wim>
I agree with you that several statements on Norbert's site will not
hold when scientifically reviewed. However I think the way you
respond will likely not result in better statements.

As the name of the newsgroup indicates; this is a radio amateur group
and Norbert site starts with "Dutch amateur radio station". This may
require another approach then you should use in a professional
environment. If you prefer that, Edaboard.com (just an example) is a
more suitable place.

Ummm... while you're working on my comments, you might also want to
make some changes to way you handle images. When you click on the
thumbnail image on most pages, all you get is an identical image with
exactly the same thumbnail size photo. In general, these are too
small to see in detail and I was expecting a considerably larger
image.

This has been a good thread, I have little room for an antenna, a mag
loop may be just the ticket for my small Tampa QTH ?

Archive-name: radio/ham-radio/moderated/crossposting
Revision: 1.1 2009/04/12 19:42:04
Posting-Frequency: posted monthly
URL: http://www.panix.com/~rram/usenet/rram/index.html

Changes followed by "|".

After a 30-day public discussion and feedback period to gauge reader opinions in March of 2009:

http://groups.google.com/group/rec.radio.amateur.moderated/browse_thread/thread/d7d337db35f23326

the rec.radio.amateur.moderated Moderation Team has decided to consider amending its charter, and permit limited simultaneous crossposting to rec.radio.amateur.moderated and one other unmoderated amateur-radio-related discussion newsgroup. We are currently trying this on a temporary basis (90 days, through early July 2009), and adopt it permanently if successful.

Approved rec.radio.amateur.* newsgroups are those that are currently listed in the latest version of the "List of Big Eight Newsgroups" which is crossposted monthly to news.announce.newgroups, news.groups, and news.lists.misc.

Approved alt.radio.amateur.* and alt.ham-radio.* newsgroups are those that have been created consistent with the suggestions in "So You Want to Create an Alt Newsgroup" at:

  http://www.faqs.org/faqs/alt-creation-guide/

Approved regional hierarchy newsgroups are those that contain either "radio.amateur" or "ham-radio" in their names, including uk.radio.amateur and aus.radio.amateur.misc.

We will make every reasonable effort to keep our list of approved newsgroups up-to-date. In case we have overlooked any, and a submission is rejected in error as a result, the rejected submitter can E-mail us at our administrative contact address (in the signature at the bottom of this article, and the default Reply-To for the rejection message) requesting that it be added, and that the article be approved. We may still choose to reject articles crossposted to any alt.* newsgroup with an inappropriate name, including obscene language, embedded name-calling, or encouragement of unlawful conduct.

Please direct any comments, questions, or criticisms to rec-radio-amateur-moderated-request@panix.com.

It is the specified diameter/radius of the 80M antenna at the link of the antenna manufacturer. I stated that quite clearly. I choose to go to the source rather than rely on possible transcription errors in amateur postings.

>I used D = 1.27m (4m perimeter), that is r = 0.635 m.

That antenna does not exist.

>Quote from Norbert's site:
>"When a magnetic loop antenna is used for 3.5 MHz with a perimeter of
>4 meter (13.3 foot) , it has an efficiency of approximately 3%."

There is no Ciro Mazzoni antenna with that dimension.

I specifically asked if this statement was for the MIDI loop antenna with a 2 meter diameter (and is designed for 80M operation). To this point no one has affirmed or denied this my natural selection from the manufacturer. The page quite clearly reveals three photos of the distinctive design. The Mazzoni antennas also come in distinctive 1m, 2m, 4m integral sizes. There is no 1.27m diameter tuned loop offering.

>Maybe this helps you to explain the difference between your and my
>result,

The original page (2) contains errors or misattribution (same thing), that is why I am careful to trim away the textual noise and restate what I perceive to be the model under investigation.

Hi OM,

Well, as you can imagine (barring the numerous errors and moral judgments), it all depends upon the band you want to operate - with the 40M and higher frequencies quite well served.

A lot of myth surrounds what are called "magnetic loops" and this thread has corralled some of them - including from Norbert as his page which forces the argument that fairly agrees that below 40M performance dives. However, through sloppy bookkeeping, the Ciro Mazzoni line is not one I would walk away from for stated "inefficiencies."

The principle consideration is the ratio between radiation resistance (power that is expressed into making contacts) and Ohmic loss (bulk metal conductivity power that is expressed into making heat). Wimpie's choice of 20mm diameter stock (how that arrived in the mix is a mystery) compares poorly with the Ciro Mazzoni 50mm tubing for its smallest design.

The 80M design from the vendor uses 75mm stock for good reason and this should be a selection guide for your application. Their second 80M design uses 140mm stock! Pushing this further with conductance now nailed down, you want a large loop because the radiation resistance varies by the fourth power of dimension. That is to say, if you double the loop radius, you obtain 16 times the radiation resistance. Small changes in loop radius can quickly escalate or emasculate efficiency. Radiation resistance is the beneficial characteristic of how we manage to couple a signal out into space and which is typically thought of as being 50 Ohms (although this is rarely the actual value that more often varies between 35 and 70 Ohms for simple wire antennas of conventional length).

As you can see from these resistance figures, the difference between a radiation resistance in the thousandths of an Ohm, and typical values in the tens of Ohms is a hallmark for caution. When paired with metal resistance in the Ohms (something that ordinarily only comes with using wire-wrap wire for long runs), you want to boost radiation resistance as high as possible. When paired with metal resistance that is in the thousandths of Ohms, there is every chance you are looking at 50% efficiency for 1 meter diameter loops.

Bigger radius comes with its own problem, however. It limits the high band of operation as these designs are optimized for being a small portion of wavelength. Observe the various design options from Ciro Mazzoni, and you will observe they are specified over only two octaves for any particular design. That should give you a clue if you want to homebrew your own, because you will encounter the same limitations of coverage regardless of construction method.

So, this returns us to the first statement above: it all depends on which band(s) you want to work. It further depends upon your pain threshold for poor efficiency if you choose to push beyond the coverage limits. Professionals describe this in terms of a cost/benefit ratio. If we restrict discussion to non-professional qualitative expressions of benefit: super, great, fantastic, maximum and peg escalating dollar amounts to each with corresponding breathless emphasis - then there are many deals for sale on those terms for the gullible.

Hello Chris,

Which antenna will fit your needs depends on many factors (tuning range, indoor/outdoor, aesthetics, local regulations, your experience/ preference, available volume, house construction, buy or homebrew, available materials, local or DX use, etc). So I can't judge whether a loop is good solution in your situation.

In addition, "the" best antenna for the transmitting case will very likely not be the best one for the reception case.

Best regards,

Wim

Hmmm.  A "magnetic" loop antenna.  Must be some other types of loop
antennas as well.  Maybe there are also "electric" loop antennas.

Guess they left something out of all those antenna textbooks I have ;-)
Sincerely, and 73s from N4GGO,

Hello John,

When you cut the loop at two opposite positions, yes, you can make
your "electric" loop.

It will generate lots of E-field, you may need another coil for
matching, and it is probably less efficient then a short straight
dipole with massive capacitive disks to get larger I*delta(le)
product.

Best regards,

Wim

Hello, and the not-so-subtle point is that there aren't magnetic, electric, or any other such "types" of loop antennas. There are just loop antennas that can further be described as shielded/unshielded, balanced/unbalanced, electrically small or large. Just like we don't transmit (propagate) electric (E) or magnetic (H) fields by themselves.

The purpose of an antenna is to radiate and/or intercept an electromagnetic field. By definition energy radiated by a transmitting antenna is not temporarily stored in the antenna's local electric or magnetic field. It's been released into free space subject to interception by a receiving antenna(s) or any other parasitic structures. The receiving antenna transfers part the intercepted energy to the load (receiver and other dissipative losses) and scatters the rest back into free space.

By contrast, a transformer, for example, is a "magnetic" device that is intended to transfer energy by a localized means (induction) other than the propagation/interception of electromagnetic radiation.

To further confuse the issue, a conductor in the near (reactive) field of a transmitting antenna will have current induced in it by the antenna's local electric and/or magnetic fields. However, that's not the usual purpose for which we design antennas. An exception might be the immoboliser (PATS) system used in late-model motor vehicles that incorporates a ring antenna embedded in the steering column that is closely coupled at RF frequencies to the transponder chip and loop antenna embedded in the vehicle ignition key. So is it a transmit-receive antenna configuration or a primary coil-secondary coil transformer configuration? Given the proximity of the inserted key to the steering column I would guess the latter. Sincerely,

Hello, all.  I should also add that in stating the above I was only
considering nearby conductors (towers, metal on buildings, etc) and
wasn't including the local directors/reflectors that may be incorporated
into an antenna to provide the desired radiation pattern
characteristics.  Sincerely,

If in your opinion there do not exist antennas that generate a
dominant magnetic or electric field (in the near field), then you are
contradicting yourself, as you can't transfer energy with a magnetic
field or electric field only. So your transformer also involves
electric fields. Maybe you should look into the Poynting theorem.

com

When a noise source is about 5..10m away from an 3.6 MHz antenna, the
coupling of that noise source towards a "magnetic" loop antenna may be

different from the coupling towards an "electric" antenna, though both antennas may produce the same far field radiation. This is not from a textbook, but from experience (I am also working in power electronics).

I fully agree with you on the far field statements, but when you live in an apartment (where significant spurious emission from home equipment are in the near field of your 3.6 MHz antenna), a so-called magnetic loop antenna may behave different (w.r.t. a short "electric" dipole). It can be worse or better. Many radio amateurs know this from experiments, without knowing the EM theory behind it.

I have no problems when people talk about a "magnetic loop antenna". It shows me that they are discussing an antenna with a circumference < 0.2 lambda. When people talk about a "loop antenna", it can be anything.

Best regards,

Wim

Text books would enlarge that volume to one half to several wavelengths for the "near field." The text books would further clarify this with math (yes, I know, professional and academic discussion in light of this being an amateur forum is anathema) and define the difference with the terms Fresnel diffraction (near-field) and Fraunhofer diffraction (far-field). The operative physical length of the antenna becomes meaningful, but this is getting ahead of what I call the "benchmark" method below.

To give the magnetic loop aficionados the benefit of this, all local noise within 100 feet would be susceptible to interfering and it wouldn't be nullable (which is a characteristic only observed in the far-field) except by polarization which is very haphazard in the near-field. I have never seen a magnetic loop mount with the necessary degrees of freedom to employ this method of "nulling." As such, the vaunted characteristic is elusive and thus becomes legendary rather than fulfilled.

However, the term "near-field" is rather vague. The more appropriate discussion is found in "reactive near field" and "radiative near field." The discussion of loop coupling to magnetic (while ignoring electric) fields would suggest "reactive near field." In this regard, the 80M volume of reactive interference is still roughly 100 feet in all directions. The "radiative near field" would encompass a volume out to 80 meters (roughly 250 feet). In either case, apartment living finds no panacea in loop antennas.

There is another, non-textual (at least to the casual reader), benchmark that such issues are measured by the physical spread of the antenna itself (this usually attends discussion of capture area to many's frustration). Here, I am returning to the allusion above of Fresnel diffraction (near-field) and Fraunhofer diffraction (far-field). The math (non-techs, turn your eyes away) is as simple as:

     2�D�/lambda

Let's work some examples from the sublime to the ridiculous on 80M.

The traditional half-wave dipole antenna that exhibits the traditional
usage for distinguishing between near and far:
     2�40�/80 = 40 meters
a smaller quarter-wave dipole antenna
     2�20�/80 = 10 meters
a tenth wave dipole antenna
     2�8�/80 = 1.6 meters
a fortieth wave dipole antenna
     2�2�/80 = 10 centimeters

Let's see where discussion follows in this regard.

what are the ones to look at that are for sale, and why ? AEA once made
one when I left Tampa and lived out west in Seattle. I live in a small,
non deed restricted house in Tampa with a flat membrane roof. I could
get a loop on my roof I suppose, if the installation looked clean.

where is your square?

Fraunhofer region starts at (22.5 degrees phase shift):

  r =3D 2*D^2/lambda

  D =3D largest antenna size (excluding structures that doesn't carry
current).

Formula is only valid for electrically large structures, so not an
electrically small loop or dipole.

For electrically small loops, reactive fields are dominant for:

  r < 0.16*lambda

Smaller loop size does not result in smaller reactive field zone. The

correct formulas you can find everywhere. To make it easy for you:
http://www.conformity.com/past/0102reflections.html shows the
complete formulas for the electric and magnetic case, and a graph at
the end.

Best regards,

Wim

Hi OM,

The specifications of the major vendors that I have seen are usually
reliable.

You still need to answer what bands do you want to transmit on? If it
is 40M and up, you are pretty sure to find a lot of useful designs.

given that I have already demonstrated that, and more, what importance
do you attach to this that hasn't already been shown?

>Smaller loop size does not result in smaller reactive field zone.

What a curious defense for magnetic antennas's noise immunity.

However, the magnetic antenna is not immune from the reactive fields
of noise emitters that are very much larger than any loop discussed
here. It is the field of the emitter that is important. I thought I
would wait and see if anyone cottoned on to that aspect of the
discussion. If we proceed with the assumption (repeated here):
>Smaller loop size does not result in smaller reactive field zone.
then the magnetic antenna is doomed to noise in the same sense as an
electric antenna is. Offhand I would speculate that in an apartment
situation, a magnetic antenna on the balcony is saturated with
reactive noise fields.

Hello Richard,

> What a curious defense for magnetic antennas's noise immunity.

Where did I mention that this relates to noise immunity? I only tried
to point you to a misconception regarding the use of the 2*D^2/lambda
formula.

```
[start quote]
> The traditional half-wave dipole antenna that exhibits the traditional
> usage for distinguishing between near and far:
>         2 40 /80 = 40 meters
> a smaller quarter-wave dipole antenna
>         2 20 /80 = 10 meters
> a tenth wave dipole antenna
```

> 2 8 /80 = 1.6 meters
> a fortieth wave dipole antenna
> 2 2 /80 = 10 centimeters
>
> Let's see where discussion follows in this regard.

[end quote]

You want to believe us that a usable antenna with size=2m and lambda=80m satisfies far field conditions at 10 cm, I really hope I understood you wrong.

> However, the magnetic antenna is not immune from the reactive fields of noise emitters that are very much larger than any loop discussed here. It is the field of the emitter that is important. I thought I would wait and see if anyone cottoned on to that aspect of the discussion. If we proceed with the assumption (repeated here):
>

The dominant reactive field from a small "magnetic" loop or "electric" antenna at lambda=80m extends to somewhat more then 10cm, think of about 5m. Though the far fields may be similar, the reactive fields are completely different in orientation, strength and E/H ratio. See for example the link posted earlier:
http://www.conformity.com/past/0102reflections.html

This will result in complete different coupling to conductors present in the reactive field zone. When using reciprocity, this will also affect the coupling from noise current in the conductors towards the antenna. So I can't follow your statement below:

>wimpie: Smaller loop size does not result in smaller reactive field zone.
> then the magnetic antenna is doomed to noise in the same sense as an electric antenna is.

Of course I agree with you for the case the noise source extends over large distance.

What antenna is better, you cannot say beforehand and is food for the experimenter (as I mentioned earlier).

This topic becomes lengthy. Do you think that it will result in better statements from other people on there websites (that was the subject of my first contribution)? The second part was just to show that the 3% claim for a 4 m loop (circumference) at 80m isn't bad.

I have real doubts about it, so I decided to send PM to Norbert some days ago to setup a more constructive discussion.

With kind regards,

Wim

Reciprocity does not appear in the text at your link and the concept
you are offering appears to be an invention that is unsupported. Let's
stick with unraveling one thing at a time.

So, working with your link's assertions give me a simple quantified
indicator of a reactive field.

Hello Richard,

As I assume you understand complex calculus, that link (http://www.conformity.com/past/0102reflections.html) was just to help you to figure out field orientation and strength versus distance for the magnetic and electrical case.

If you still believe in the 2*D^2/lambda far field formula for electrically small antennas, I doubt whether it is useful to continue.

Best regards,

Wim

> electric fields. Maybe you should look into the Poynting theorem.

Hello, and that is correct. The Maxwell equations apply in all these cases. When solving such problems, especially when dealing with antennas, the total E-M field contains both reactive (electric/capacitive & magnetic/inductive) and radiative components, although certain components predominate depending on distance from the excited structure.

When dealing with A.C. circuit problems where dimensions are a fraction of a wavelength, one can usually ignore the the radiative/propagation components. Why solve a problem with a sledgehammer when a small claw hammer is adequate? Wouldn't you rather use Ohm's law in such case rather than dealing with E and H fields? For example, the behavior of A.C. power power distribution lines operating a 60 Hz can certainly be modeled using transmission line equations but unless they're very long (implying a propagation delay), a lumped-element/circuit approach is much more easily dealt with (lumped lines. And yes, I'm intimately familiar with the Poynting theorem and its derivation. (The designers of the CFA obviously weren't).

There's no such thing as "magnetic" and "electric" antennas. The marketing departments of antenna vendors or others can call these whatever they want but they can't change the laws of physics. Now, if one dimensions a loop antenna or dipole antenna small enough (compared to a wavelength, one obtains a magnetic or electric dipole, respectively. Such dipoles (note the absence of the word "antenna") are a theoretical concept but can be applied in practice to those structures having electrically small radiators/interceptors.

Hey, I'm a fellow Ham and well aware of the contributions over the years by hams to antenna design. Many times, however, established electromagnetic theory is distorted to match the perceived observation.

In the case of noise immunity I would discuss the size of the victim antenna, the antenna type (e.g. loop or dipole), antenna dimensions, orientation and proximity wrt the offending noise source, and whether the victim antenna is shielded and balanced. Unless one is referring to an electrically small antenna treated as a magnetic or electric dipole, typing an antenna as "magnetic" or "electric" is meaningless.

Whoops, we have to be careful to not getting involved in a new discussion, but I agree on your statement regarding that "special" antenna and the statements regarding whether or not to use distributed versus lumped circuit approach.

>

>
> There's no such thing as "magnetic" and "electric" antennas.

That is why I added the word "dominant", as you can't transfer energy with H or E only and we were discussing small antennas as shown on Norberts website.

One may imagine the electrically small magnetic loop antenna as the primary of a transformer where there is no secondary coil in the reactive field. The RF leakage (far field radiation) by accident hit the antenna of another amateur.

The

I agree on the above. Let I mention the two letters "EH" in addition
to your three-letter combination to avoid a new discussion...

So from twice to infinity. Still not a quantity. You seem to have the
same problem for which you berate others.

OK, so you cannot present a simple quantified indicator of a reactive
field from your own source.

It is quite apparent without going into math (I thought that appeals
to professionalism and academics like complex calculus were verboten
here) and I see it quite plainly ILLUSTRATED in Figure 3.

However, if you cannot vouchsafe for this source and agree to what it
represents, you are right, there is no basis for discussion.

>If you still believe in the 2*D^2/lambda far field formula for

I wish you wouldn't interpret beliefs and simple stick to what I've
written.

2 (twice) is not a number? The antenna most frequently discussed is a 40th wave or 2 meters across. These are two more numbers (40th and 2). Twice that yields to more numbers (20th and 4).

Infinity is not a number.

You didn't say twice. You said "twice - at least". So what number is
that, Dick? I was taught that the phrase represented a range, not a
number. All you did was put a lower bound on a number you don't know.

>All you did was put a lower bound on a number you don't know.

>> However, the magnetic antenna is not immune from the reactive fields
>> of noise emitters that are very much larger than any loop discussed
>> here.

Choose a "loop discussed here," and you have a number (1, 1.6, 2, and 4). Double (at least) that number, for that loop, and you have a new number for the noise emitter (2, 3.2, 4, and 8). If you want to more than double the original number (1, 1.6, 2, and 4), there are probably practical examples of noise emitters for those numbers too.

The lower bound works as a practical matter but is not exclusive of other practical, larger emitters. One common example would be the standard 80M dipole which would give you a number of 40, but that is not the upper bound.

So, having said double (2, 3.2, 4, and 8) at least (which allows up to 40 which is more than twice any previous number) and there being larger numbers that satisfy the observation, the larger numbers become an issue of practicality, not number. There are Rhombics (certainly impractical for many) that have dimensions of 320 meters:
http://www.pa6z.nl/PROJECTS/ANTENNAS/RHOMBIC/body_rhombic.html

I suppose now the point to argue is "Is 40 (or 320) very much larger than 1?"

For the benefit of Wimpie and beliefs: "I would believe so, although I am open to convincing argument that 40 (or 320) is NOT very much larger than 1."

I have a tree here in the Tampa Florida area just begging to have a Hustler 4 or 5 BTV stuck in it. I have had great luck with ground mounted Hustler Verticals when I lived near the sal****er of Tampa Bay. I am now in Brandon Florida, east of Tampa, and far from salt water. I have stuck Hustler Verticals in trees before with radials for most bands, but had access to a bucket truck back then, and did not have stents in my heart. I got to thinking WHY not take a hustler vertical with only ONE Tuned "radial" for each band in the form of the lower part of a 1/2 wave dipole. In other words, make the Hustler Vertical into a multi band center fed 1/2 wave dipole. It will be a lot easier to deal with only one radial for each band if they hang straight down the tree vertically. Has anyone ever done this before ?

It would work, but the lower radials would have to
be spread apart to avoid coupling issues.
One could also just hang a second trap vertical as
the lower half of the antenna..
But, being I am a radio bully, I tend to avoid trap
antennas. Hustler verticals are pretty lossy on the
lower bands when you factor in the loss of the traps,
and then the upper level loading coil required to
resonate the thing.
If I were to use a commercial antenna to do what
you propose, I think I would prefer a Butternut over
the Hustler. :/
But anyway, what you want to do will work, but it
would be best to angle the radials a bit away from
each other to minimize coupling and the tuning
difficulties you would see if they are very close
to each other.
Also, the amount of ground loss will depend on the
antennas height in wavelength. So I wouldn't expect

gangbuster performance on the low bands unless the
antenna is very high. And how high must be determined
for each band measured in wavelength. High on 10m,
might almost be considered on the ground on say 80m.
So the amount of radials needed for an equal amount
of ground loss will very greatly to the frequency.
So if say the whip base is at 20 feet in the tree, and
you are hanging an 8ft radial for 10m, the performance
should be fairly decent. The antenna is up at nearly 3/4
wavelength, and one radial will do well.
But on 80m, 20 ft is just barely off the ground at
less than 1/10 WL high and the tree is not even tall
enough to hang it vertical. It would need to be run out
at an angle, and with only one radial at that low height
in WL, performance is going to be lame.
Of course, if you can mount it higher, the frequency
where lameness creeps in will slowly drop as you get higher.
:/
If I wanted to work all bands, I'd use the tree as a
support for an all band horizontal dipole.
Or even better, parallel fed full size dipoles, which
is what I usually run.
It would do a better job in the overall scheme of
things. You would have a semi decent NVIS pattern on
the low bands, and still be able to work some DX.
With stunted vertical on the low bands, NVIS performance
will be pretty lame. Many of the guys just running
plain Jane low coax fed dipoles will be kicking sand in
your face on the shorter lower band paths. :|

You are trusting that each radial will be resonant on only one band
akin to a fan vertical antenna. What may happen, for instance, is that
the 40m radial may accept an appreciable amount of energy on 15m and
direct the 15m signal up at a high take-off-angle - less than optimal
for 15m operation. Other interactions are possible, e.g. 28MHz/4MHz=3D7,
18.14MHz/3.6MHz=3D5, etc. Any vertical radial resonant at 3/4WL, 5/4WL,
7/4WL, etc. will have a suboptimal effect on the take-off-angle.

>A wire trapped dipole would be easier to hang vertically in a tree.

Hi OM,

There are at least two difficulties with this - even though it sounds eminently simple.

One, the two arms of the dipole have an uneven balance with ground. This means that given the typical configuration of trap design and placement, that the traps on each side must be different to account for the lack of symmetry. In an ordinary horizontal placement, this is not a problem.

Two, the standard advice for the feedline in a horizontal dipole is that it drop away at a right angle for at least a quarterwave before being turned in its route toward the shack. Well, the feedline still has to drop away from the feedpoint, but with the antenna vertical, this means it has to first move horizontally a quarterwave before dropping and THEN turning towards the shack. This is unlikely to be a practical construction, or you would have simply put up the dipole horizontal in the first place.

The feedline trailing down alongside the lower arm of the vertical dipole is going to seriously interfere with tuning and launch angle. In a sense, it will be shorting out any traps in that arm.

This is why I offered the GAP line of products as an example of a vertical dipoles. They are not the only line that offer a solution to the problem of the feedline proximity. What they do is route the feedline up INSIDE the lower dipole arm. Physics insures that the inside of the arm is shielded from the outside. However, there is still the problem of coupling at the lower tip (where the line enters to go up). GAP puts a W2DU style choke there.

Now, as to your point of "hang vertically in a tree" suggests that the GAP style antenna would be hung from its upper tip, rather than mounted (electrically isolated too) at its lower tip. I'm sure you could come to terms with that.

I never considered this Cecil. Would you think it better to use a wire
trap dipole instead of the Hustler 4BTV
and hang it vertical in the tree ?

Changes followed by "|".

The rec.radio.info newsgroup, first established in 1993, has been

recently revived by an active moderation team. We are currently seeking
suitable information, FAQ, and bulletin articles from the entire
rec.radio.* newsgroup hierarchy for simultaneous cross-posting to our
newsgroup.

We are seeking a replacement maintainer for the following information
bulletin formerly posted to rec.radio.amateur.* (and currently archived
at http://www.faqs.org/faqs/radio/personal-intro/):

 radio/personal-intro
 Subject: Guide to the rec.radio Newsgroups

" Using such a pulse pattern makes the echo, which arrives back from the moon 2.4 seconds later". From: http://www.rense.com/general79/haarp.htm

"During the experiment, which was carried out on Oct. 28 and 29, 2007, the radar signals from HAARP were at 7.4075 MHz and 9.4075 MHz"

I do not know the distance to Moon on that days but for the mean distance 384 000 km the speed is:

384 000/2.4 = 320 000 km/s.

Speed of light is 300 000.

But long waves travel quicker in glass. Would be the same in space?
S*

No. Maybe I don't understand the complex calculation under your quoted division by 2.4, but....

Your "mean distance" have to be doubled: received *back* in 2,4 sec mean that the signal traveled the double distance.
At minimum distance the moon is 356375 km far from earth. 356375*2 is 712750 km, that at light speed means a travel time of 2,37 sec.

Any greatest distance agree with classical physics laws, and a normal mind don't care if the light travel faster, maybe care about the distance of the moon at the time of test: exactly 360000 km from the earth.

Don't you ?

i'm glad you checked their calculation and found that obvious error...
i guess all the other radar calibrations in the world have to be
changed to account for the bialek speed effect... i wonder if that
would get you out of a radar gun speeding ticket?

The test was made at "full Moon". ""Even though lunar echoes have been
detected before at higher frequencies, it was really exciting to see them
arrive in real time out under the full moon in the New Mexico desert,"

I do not know the distance. But some radio amateur practice communication
via Moon. Have they own observations?
```

>
> Any greatest distance agree with classical physics laws, and a normal mind

Now are transmitters on the Mars. They are able to give the answer for
Maxwell. He wrote:
" " Incidentally, Maxwell once suggested that Roemer's
method could be used to test for the isotropy of light speed, i.e., to test
whether the speed of light is the same in all directions. Roemer's method
can be regarded as a means of measuring the speed of light in the direction
from Jupiter to the Earth. Jupiter has an orbital period of about 12 years,
so if we use Roemer's method to evaluate the speed of light several times
over a 12 year period, we will be evaluating the speed in all possible
directions (in the plane of the ecliptic). " From:
http://www.mathpages.com/home/kmath203/kmath203.htm

As you see Maxwell care if the light travel everywhere with the same speed.

The same is with the wave lenght. Longer water waves travel faster. Is it
the same with radio waves?

I have, at another amateur's station, on 432 MHz.  Surprisingly the
speed came out almost dead on 300m/microsecond.  Used .wav file
recording of transmit and echo and a good sound file editor with
sub-millisecond resolution when zoomed.

Surprisingly?

You were thinking that propagation might be at some other rate?

the dominant error source in your measurement is probably the sound card's clock.

For other fun measurements of em propagation speed.. melting the mode pattern of a microwave oven cooking chamber at 2450 MHz into a single layer of marshmallows on a plate (turning off the rotating turntable and mode-stirrer, of course). Chocolate morsels might also work.

Other methods, for visible light, include the spinning toothed wheels of Fizeau and rotating multifacet prisms of Foucault (later updated by Michelson)

Interference fringes from a laser, as well.

if one is looking for more "radio" than "light".. look at the doppler effect from a moving source. The fractional change in frequency is equal to the velocity/propagation velocity.

If you do something like measure the frequency from, oh, an orbiting satellite and get the whole "doppler curve" you can figure out the frequency of the oscillator (it's the frequency at which the second derivative of measured frequency goes through zero). You can measure the velocity of the satellite optically (if you pick a satellite which is visible, like ISS)

With implied facetiousness.  Should have been more obvious I guess.

10m dish with full legal power, BTW.  Very good signal to noise.

I have checked the Moon history and now I know that on Oct. 28 2007 was
"full Moon" at perygeum. So the speed was close to 300m/microsecond.

But I am steel loking for the evidences that the speed of radio waves is
temperature and wave lenght dependant.

Norton may be trustworthy. I say that in spite of your feelings
because for my friends who use it, they do not suffer any attacks.
However, they do suffer from its huge resource drain and my friends'
most consistent complaint is how SLOW their system is.

Norton sucks the air out of performance.

Myself, I use Comodo for its firewall (and turn off its virus
detection); and I use AVG (free) for virus detection. I also use
Process Explorer (a very elaborate Task Manager) to look at the system
usage. Even as I write this, my system has 96-98% CPU capacity left
as it should. Any AVG process barely demands more than a quarter
percent CPU cycles.

Shouldnt be a problem, You may want to search  for NVIS antennas. I do
a fair amount of camping mostly in the mountins of NC, Ga, TN, VA and
WV. This means camping in the valleys. Seems the NVIS antennas work
better from these locations. Many can also be improvised from local
materials.

Jimmie

"Norton sucks the air out of performance"
I agree!

I had a family client that I set up with AVG Free. It failed,
situation beyond my skills, reload XP Home required...
Maybe it would have done the job if I had opted for the pay version.

One big difference is that the hybrid in a POTS phone doesn't want a
deep null. They want enough left of what is called "side tone" to give
feedback to the ear with receiver on it. If you don't they are
uncomfortable and also think the call has been dropped. It would be in
the -10 to -30dB range I'd guess.

On the other hand the null for this antenna array would need to be maybe
90dB or better to be really useful. Maybe with processing it could be
done with less, but I'd have to say, I don't know.

Bullshit. I've seen Norton totally fail. I'm an IT guy that repairs this stuff, and IMHO Norton itself is the same as a virus in many respects.

Its not true that 'everyones' suite sucks out performance, but as you say, Norton sure does.

All most SUITE software is nothing more than an in-house firewall that is substituted for the stock MS firewall.

Here we have three (3) antennas, and as we all know they are not in
isolation.

Somewhere, there's a nearby (or near enough) overlooked reflective
surface that disrupts that oh-so-absolutely-necessary symmetry.

That's a fairly close assessment. :/ I'm running Norton Suite here,
mainly because I get it from Comcast. So far, I think it is
doing a better job at blocking terrorists than the McAfee suite
that Comcast used to use. I got whacked pretty bad once when running
McAfee suite, and the byte terrorists bug actually turned off and
disabled the McAfee suite. I finally got that cleared up, but it was
one of the hardest infections to totally clean up I had run across
so far. So far, bang on wood, Norton suite has not let anything through,
and in fact has caught a couple of bugs since I started using it.
I don't find the Norton Suite a constant resource hog, actually very
low most of the time. But.. I sometimes notice short term slowdowns
when it's doing one of it's processes. IE: new sig downloads, scans, etc..
Sometimes I'll see it when watching a movie. It will freeze or jitter
my video for a second, then the load idles back down. It never lasts
longer than a second or two. I've always assumed Norton was causing that,
being as there is no other real reason for it. And I'm running a quad core,
so no real lack of horsepower to keep up with the video.

So I can tell something pulls a momentary hard load every once in a while.
I used to use AVG, but quit for some reason I can't even remember..
Seems they went to a new version or something and I decided to switch to
the suites being as I get them pseudo free from Comcast.
But in the overall scheme of things, the puter runs the same as it
ever did.. No constant slowdown at all.
Right now I've got 9 browser windows open, mail, Windows Explorer file

manager, and still idling along at an average 1-2 % CPU use.
You can see some spikes, but a lot of that is moving the mouse, etc..
So far, bang on wood, nothing has been able to whack me since I have
been using the Norton Suite. I'm sure there is always a first time though. :(
I never feel totally invincible no matter what I'm running.

many years ago i built a motor that was powered by only a wire
sticking up about 20' in the clear air... very interesting free
power!  but very dangerous near thunderstorm!

In clear air the electrons migrate up. Under a cloud down.
The direction of DC is weather dependent.

Of course sometimes no DC at all.

It is interesting that a wire sticking up about 20' produces DC but your
antennas no.

Transmitting antenna is like electron gun.

SB,

If electrons leaving the antenna are what makes it work, then please explain how an antenna coated by an insulator like plastic or fiberglass works.

Yes, everything can fail. I cannot forget the time when a Norton update shut me down. It was a long ways back and I don't remember the details, but it was not pretty.

I am an old retired guy who has fallen into the trap of maintaining a few family and church machines. Usually on my funds and always on my time. Since I have a lot of more interesting stuff to do I like to keep things simple as possible for me. Norton has 3-user packages that are available on sale from time to time and I am the only one that notices the performance hit. The background scans seem to be the worst offender for me. I tend to run too many browser windows open at any give time. Saving & restoring Tab groups has helped a lot there.

It is a good time for an old geek to be retired. Information is widely available and lots of good guys to communicate with!

BTW and even further off topic, my clothes washing machine failed early this week. I found a wealth of service info on YouTube which saved me about $500! I will take me a few days to recover from the physical efforts but it has been a very satisfying week!

Hopefully I will get some maintenance done on the tower this coming
week and get back to antennas...

Permittivity is material and frequency dependent. The space and an insulator
like ice and plastic or fiberglass have small value.
Water has 81.

An antenna covered with ice works. But if the ice is melting and the all
pores are filled with water the antenna do not work.

The key issue is the net DC current. Of course as a result of ansymmetry.
More electrons flow up then come back.

This net result is easy to measure.

It was here about antennas made of salt water.
Is it a normal practice to make an underwater antennas?

yes, there are underwater antennas in use 24/7 by military
submarines... so how do the electrons get through the salt water?

They don't. Radio waves travel through water the same way they travel through outer space. Albeit better through water at ultra-low frequencies.

I don't see where you explained anything about the electrons. The article doesn't, either.

I'll repeat the question in case you forgot it again.

"so how do the electrons get through the salt water?"

And of course then we have the problem of RF communications with people who are in caves.

How do the electrons get through the dirt? Which seems to be even less likely than salt water.

Having not read most of the nonsense that attends this kind of side thread, I will dip my oar into this anyway and ask:

How do the electrons get through the air? (especially when, in their ferocious struggle, they usually light up the night with corona in the best of worst performance that rarely achieves propagation beyond an inch).

About 25 years ago, I attended a conference on design methodologies
for blanking continuous (or high duty factor) signals in a military
environment.  The benefit is to eliminate interference by your own
transmit signals to receivers, especially wideband EW/ECM receivers.
No discussion of twinned transmit antennas, though, but sample-and-
cancel techniques were prominent.  Big problem: maintaining phase
linearity.

Asymmetric molecule oscillations = sound waves.
Asymmetric electron oscillations  =  electric waves.

On that page are radio waves in air and water. Free electrons are
everywhere. But the freedom is material dependent.

In Nature are the continuous flows and the oscillatory flows.
The oscillatory flow is a second name of waves. If oscillations are
asymetric than net flow take place.

Electrons are everywhere. Their freedom is material dependent.

but then why can't i measure dc current from my antenna?  and why do
my oscillations look so symmetric?

<sobars@cox.net> wrote:

>Big problem: maintaining phase
>linearity.

I was on duty aboard the USS Holland (my job, heading up the standards lab) when one of the submariners rousted me out of my rack to make a measurement - the last one before the captain could go out to sea.

I tumbled down the ladder (sometime in the early AM) to find a group of techs huddled around a meg-Ohmmeter in the main passageway just aft of Sherwood forest.

Now I add that significant detail because, as you mention about maintaining phase linearity, every time a sailor shimmied past the group to go forward, his movement would peg the meter in one direction or the other. The guys were trying to measure a gigohm load in the nuclear reactor. The disturbance of the local electric field was enough to drive the resistance bridge wild. Any movement in its vicinity was enough to do that. There was barely enough patience among that group to let anything settle.

The sub couldn't move until they got at least 1 Billion Ohms, and when I asked what the problem was (I was the pro from Dover there to rescue their butts or the captain would keelhaul them), they said they were several magnitudes of order off - too little resistance.

I hunkered down over the instrument, waited a couple of minutes before the static fields settled and the instrument calmed, and I measured AT LEAST a gigohm. "So what's the problem?"

"We need a billion ohms before we can certify the reactor is ready to get underway!"

I looked at my measurement - easily a billion ohms, 1 gigohm (I thought there wasn't that much resistance between us and the moon, but

I wasn't going to make that observation with the XO hunkered down
watching this, and the Old Man staring over his shoulder.).

"No, No! A BILLION OHMS!" came their plea when I pointed out the
measurement.

"What do you think a billion is?" I asked.

"We looked it up in the dictionary and its a million million."

I stood up and looked forward to crawling back into my rack. "That is
the English definition for billion. What you want is the American
definition for a billion which is a thousand million."

Normal level on a phone is about -25db I think sidetones are about 10
or 12db below that. Take that with a little salt my comm days are long
time past.

To measure it you must have an equipment and good will.
The last is more important.

Look at the original Hertz apparatus:
http://people.seas.harvard.edu/~jones/cscie129/nu_lectures/lecture6/hertz/
S_p11.gif

To have one portion of radiation it is enough to charge one half of the
dipole. Charging is made with DC.
After some time you can repeat it.

The radiation is in form of  the damped wave:
http://en.wikipedia.org/wiki/File:Ondes_amorties.jpg

In damped waves each amplitude is smaller than the previous. So in one cycle
no symmetry.
```

It is obvious. But you can try to detect it.

can't detect it here, my waves look like perfectly symmetric sine
waves and i can not measure dc on antenna.  how much dc should i have
with 1000w at 14mhz?

I do not know. It is peak voltage and efficiency dependent.

If electrons jump off from antennas it will be easy to measure in klystron:
http://en.wikipedia.org/wiki/File:Klystron.enp.gif
```

The electron beam is collected after work. If starting beam is equal to
collected then no jump off.

i have worked with klystrons... the current in equals the current out,
all electrons are accounted for.

"...most people that are creative people...are pretty much different from the average person, they don't think the same way, they're not motivated by the same things and...they're usually very very difficult people to get along with. ...they're not like you or well most of us." [The Summer of 2010, 3840khz (2:30 in the morning), Comment from Jim (KI6GU) A rare qso on worldviews].

"Just relax a little bit...c'mon Kevin. Ya know laid there four days on the floor, ya know and you're alive. Ya gotta be thankful for that. C'mon man, if somebody at your work didn't have a reason to care about you a little bit. You wouldn't be here with the rest of us. Now you gotta be thankful for that c'mon. Lotta people have their problems and have their issues in life. Everybody's not the same mold, everybody's different, everybody's built different, everybody has different wants and needs. Some people need somethin' to hang on to too make 'em feel better. Or people...ridicule other people because they don't feel good of themselves unless they do ridicule someone. Just c'mon...man. Just relax." [The Summer of 2010, 3840khz (2:40 in the morning), Comment from John "Cosmo" (KI6VPR) to AD8Q on cooling Kevs nerve because somebody did not identify].

Jim's comment from the summer of 2010 (Tom sat back on this qso) alludes to the youthful mindset of, shortwave maven, Tom Gleeman's (KE6YNH), friendly personality gift. One of the nicest ham operators to operate from the Pacific shores. Tom has passed on from a massive stroke at the age of sixty Feb. 12 2011. (see source)

Tom Gleeman was one of the original founders of the late morning frequency rag chew - on 3840KHz, one created by the semi-retired broadcaster Art Bell. I will never the first time I tuned in and found Tom and Kenny (fondly known as the Llama Man (KG6HKM) in a 2AM qso, anybody's who was fortunate to hear Tom and Kenny in a solitary qso, were reminded of the characters from Cervantes novel "Don Quixote". Odd confessions like Tom admitting that in all the years living in San Diego "he never surfed but only boogie boarded [with his spontaneous chuckle]", exemplified his earthiness. Both Kenny and Tom in qso were classic examples of rag chewers. I will never forget Tom's "Annnnnnyway" punctuation and his distinctive youthful sign "This is Tom innnnnn Sannnnn Diiiiiiiiego" .

Tom was proud of his Chinese pen pal girlfriend, a knowledgeable

Trekkie, loved his dog (who got stuck in the dog door),
his cat, hated the 500 pound concrete table that rusted in his back
yard, and was very grateful to the American Radio Relay League (ARRL) in
addition to respecting the old dogma of shortwave communications,
he lived life to the fullest.

In the last seven months his probing conversations that at times were
taken out of context. In all sincerity, and from I what I've heard from
his qsos, his so called, contorting statements occurred when he started
taking pain killers. Somebody on qrz.com noticed the subtle change too.
Tom was more like a moderator, keeping other hams at bay from killing
each other, but at times he would rather lay low through the occasional
war zone that would erupt on 3840kHz.

Somebody at the qrz.com obituary commented Toms fondness for calling
cq. "This is Tom calling cq, calling cq, this is KE6YNH calling cq"
sometimes I heard him do that for 10 minutes and usually he'd get a
response. Right around Christmas of last year Tom commented that his
earliest memory when learning about ham radio was "he always wanted to
call cq" and was amused when he roused a senior ham from his sleep who
chastised him "Don't ever call CQ. It is a thing of the past." Always
grateful to make making a contact he acknowledged ham operators from
the East Coast of the United States, the Midwest, Alaska, Canada, South
Africa, Hawaii, Australia, New Zealand, Mexico, Central America, Japan
and Costa Rica. What was interesting about Tom's personality, he
admitted that he would sometimes talk with non licensed operators who
were respectful and had something to say. That was so cool and
represents the young'un hams who did eventually get their tickets
because of Toms encouragement.

Let us now celebrate Tom with two nice musical selections.

Shelly Y Nueva Generacion - Vestido Azul [1966]
(http://www.youtube.com/watch?v=9bRTq3t7q0U)

The Staple Singers - Be Careful of the Stones You Throw [1964]
(http://www.youtube.com/watch?v=vBthgVHdy0g)

A moment of silence was called at Feb 18, 2010 2:29 A.M. (PST) on
3840Khz by a stellar group of fellow hams.
My condolences to Toms survivors.

So in your area the field emission do not work.

Field emission is voltage dependent. What is the voltage peaks on the end of
your antennas.
Even if they are symmetric the emission is different for negative/positive
voltage. The negative emission is stronger.

Put on CB antenna the cathode ray trap (vacuum tube) and measure the
anticathode to ground current.

Been done.
Adaptive cancelers for co-site interference have been around for
decades. A friend of mine used to work for American Nucleonics Corp
(there's a company name from the 50s, eh) in the 80s, when they were
transitioning from totally analog cancelers to digitally controlled
cancelers (with the canceling still done in analog, with a second antenna)
The idea of two transmitting antennas forming an adaptively canceled
null at the receiver has certainly been mentioned in the literature.

All practical systems like this use some form of adaptive logic to fix
that.  Usually, adaptive canceling is done in the receiver, because the
signal levels are lower, but in the 802.11 kind of world, with 100mW
linear transmitters, there's probably not much cost difference.

A different matter if you're running a kilowatt.

how can it be voltage dependent if it is necessary for the rf signal?
do qrp signals that only generate 1v on the tip of the antenna not
generate rf waves and propagate??

oh yeah, riddle me this... infra-red light is another form of
electromagnetic energy which can be picked up from the heat of your
body by an IR camera... since your body is radiating em waves
continuously why aren't you always charged??

It only takes a couple of milliWatts (kiloWatts aside) to ruin your
day in competition for listening to microWatt signals. The desired
signal's transmitter antenna would have to be literally within the
near field of the active transmitter (and receiver's) antenna system.
At that point, we may as well use a land-line with hybrid bridges.

Software coming to the rescue for a hardware problem works only in
multi-million dollar projects (fly-by-wire avionics comes to mind).

In these sorts of systems (the ones alluded to in the original news story), all the signals are in one FPGA (in digital form) and the powers are fairly low so all the RF stuff runs basically linear (DC to RF efficiency isn't a huge deal on a 50mW transmitter next to a 10 Watt FPGA)

So it *is* a wireline hybrid bridge.. but done with numbers instead of transformer windings.

The point I was getting at is that in these MIMO systems, there's already multiple receive and transmit channels with substantial signal processing going on. So it doesn't really matter much whether you do the cancellation/null forming in the Tx or Rx side. If you can do some clever canceling with Tx, and make it possible to use a cheaper Rx (or, run full duplex without needing huge dynamic range/linearity in the Rx) then that's probably a net good.

The technique proposed is very, very similar to one used to create increased stereo separation ("headphone sound") from conventional stereo speakers. You send a part of the Left channel signal to the right speaker that just cancels the signal arriving at the right ear from the left speaker. It's a very, very impressive effect.

Hi OM,

I especially like your coverage of your antenna from I3VHF.

On your second page, unfortunately, you have some misconceptions about loop antennas.

All antennas exhibit the same noise characteristics.   If you erected a conventional (electric) dipole in the same space, it would exhibit the same characteristics.

It is quite curious how you describe a front/back ratio for a dipole (the loop is a magnetic dipole, and as such "should" show a conventional dipole pattern).

As for loop efficiency, you state:
     "When a magnetic loop antenna is used for

3.5 MHz with a perimeter of 4 meter (13.3 foot) ,
it has an efficiency of approximately 3%."
Please show the math.

This seems to be straying from what this is about: an antenna system.
You seem to imply that the 10W FPGA is a source of radiation to
confound things. How that arrived, I don't know.

The presence of uncontrolled reflecting surfaces in proximity to the
antenna system is the objection, and the introduction of unintended
out-of-phase reflection transmission signals combined with intended

receive signals present at the receiving antenna yields the classic
problem of S+N/N degradation.

>So it *is* a wireline hybrid bridge.. but done with numbers instead of
>transformer windings.

This does not answer the objection. Reality (conventional usage) will
bring these corrupting out-of-phase signals and the best that software
can offer is a regression of retries to obtain error corrected packets
sorted out a the cost of seriously depressed through-put rates.

This "invention" is more about being clever than useful and belongs in
a museum case next to the Babel Fish (whose utility is questionable
when you have to listen to Vogon poetry).

Hi Richard,

Thank you for your reply and your interest in my homepage. I will answer
your questions between the lines.

I will use the remarks that I get to improve the content of the article on
my site.

> Hi OM,
>
> I especially like your coverage of your antenna from I3VHF.
>
> On your second page, unfortunately, you have some misconceptions about
> loop antennas.
>
> All antennas exhibit the same noise characteristics.   If you erected

> the same characteristics.
>

I agree that they are electrically equivalents. However, my point is that the magnetic loop has useful benefits over the dipole antenna for RX under certain circumstances. I believe the magnetic loop construction will in many cases deliver an acceptable signal at the receiver with less disturbances such as atmospheric noise.

About external noise sources:

The loop is smaller (less surface) and therefore picks up less static noise. The dipole covers a larger area in which there can be sources of noise.

The pickup loop that connects the coax to the loop antenna is isolated from the antenna and it forms a shortcut for DC. The signal transfer is inductive.

The magnetic loop tunes to the frequency and there is no external antenna tuner needed.

About intenal receiver noise and mix-products:

The magnetic loop in itself is a band pass filter at the source of the receiving signal. It eliminates strong signals outside the received frequency. Therefore the receiver can receive the wanted signals with maximum sensitivity. The band pass functionality of the loop protects the radio from overloading. And as a result of that the radio will be quiet and doesn't need to pick a weak signal from an overloaded band. The bandwidth of the I3VHF is very small in the 40 m band. AM modulation is not possible as the bandwidth of the loop is too small here for passing a standard AM signal. The signal will be clipped and the transceiver react to that which can be seen on the SWR meter. SWR starts to alternate on the rhythm of the modulation. The bandwidth of the antenna gets larger in the higher bands. I believe that in the 40 meter band the I3VHF only lets trough one frequency in SSB. The receiver is almost mute tuning higher or lower.

As for receiving the readability is more important than signal strength. The lower RX signal from the magnetic loop is often more readable than when using a full size dipole at ideal height. I think that the advantages are best in the Low bands, e.g. 80, 40, 30 meter.

For TX there are advantages of the magnetic loop over the full size dipole.

When one has shortage of space. The high small band pass filter that the Magnetic Loop is, makes the radiated signal free of harmonics. Therefore there is a smaller chance of rfi to be expected .

Maybe some of the points here are not based on solid scientific research. But it is what I found doing experiments with the loops.

> It is quite curious how you describe a front/back ratio for a dipole
> (the loop is a magnetic dipole, and as such "should" show a
> conventional dipole pattern).
>

The data is based on the specifications of the manufacturer of the I3VHF loop antenna.

http://www.ciromazzoni.com/English/Loop%20Antenna/Loop%20Baby.htm

In the manual, page 42, 43 there is a picture of the radiation pattern:

http://www.ciromazzoni.com/English/Loop%20Antenna/Manual.pdf

It also surprised me as I expected a dipole pattern.

> As for loop efficiency, you state:
> "When a magnetic loop antenna is used for
> 3.5 MHz with a perimeter of 4 meter (13.3 foot) ,
> it has an efficiency of approximately 3%."
> Please show the math.

The 3 % efficiency is hypothetical based on the outcome of calculations software that is available on the Internet.

For example the loop calculation software of G4FGQ.

To be polarized must be the two poles (nodes). Long wire antennas have many
nodes and the directional pattern.
```

Is it right?

What is this thread? Where did it come from, and what is it doing in
rec.radio.amateurs.boatanchors?

We don't care about your packet radio nonsense. If it doesn't have an 807
final at least, it probably doesn't belong in this newsgroup.

Sadder yet is the fact that the OP doesn't seem to realize that it's the
responsibility of the control operator of the originating system to make
sure that the traffic is suitable for sending over amateur radio.

And saddest of all is the OP's seemingly random selection of newsgroups,
especially when he chose to identify himself as "no.spam@no.spam."

The tip of a monopole and its base are its two nodes. A monopole is polarized.

This is a very simple lesson to learn.

but, but, but, the base is a voltage minimum, not the opposite peak
voltage of the top!!!  how can that form two nodes to make the
electrons jump opposite directions?  this just can't be true!  this
must only be half polarity polarisation.

What?  Is this Oliver Twist in reverse polish notation?
```

"Please, sir, can I have another node?"

Yes, you have fully anticipated an objection in its juvenile form.
This can be countered (after asking for a hand to be held out for
switching):

Pick any potential reference point along the
length of the quarter wave monopole;
every point above it will have the opposite polarity
of any point below it - ergo, two nodes are described
each on either side of the reference.

I hope I don't have to explain that using batteries and resistors (it
may present a challenge in introducing advanced electronic concepts).

I agree, just put it up, feed it with open wire feeders, tune it and
talk. What you get is what you get.

Half polarity = no polarity.

The field emission take place where the voltage exists. But at the end the voltage is doubled (standing wave). So the strong radiation is only from the nodes.

Such situation is also close to the base. But there no voltage. No voltage
no field emission. On the quarter wave monopole is only one place with very,
very high voltage. The dipole has the two.
>
> I hope I don't have to explain that using batteries and resistors (it

The "shape" of the node effects the emission. Thin wire radiate in different
direction than a hat .
But in the elongated node every point have the same polarity.

Faraday is great.

so if there is only a single high voltage point at the top how is it
vertically polarized and how does it radiate at all without the other
half of the dipole?

but on the other half of the sine wave the polarity is reversed...
then what happens?  do the electrons get sucked back in?

then what happens?  do the electrons get sucked back in?

Of course. But the longitudine waves transport mass (electrons) and are not
symmetric. Jumping off is stronger than sucking  back.
Tesla discovered the catode rays (electrons) jumping off from the antenna
end. It is the net DC ground current. Why you do not to measure it.
It is known how to collect the catode rays.

half of the dipole?

You probably have seen the CB radio. On the end of the whip is alternate
high voltage. It radiate the longitudinal electric waves. The other half of
a dipole is chassis (car). Is there any polarisation?

That should explain things a bit more - it's really sounding like he's
spent a little too much time with the TNC. I've seen this happen before
when someone doesn't unplug themselves from the shack.

KG6BAJ, if you're reading this, spend some time away from the radios.
It'll help to readjust your perspective.

- J.

I've figured this out. :-)

The original posting is from 1995, when people still cared about packet radio
and to many usenet was new and exciting. The reason it took so long is that
it was behind a posting of a shack photo sent as a .BMP (windows bitmap file)
and it took 15 years to be transmitted.

It then ended up in packet to usenet gateway, which added the modern headers.

Geoff.

Dave I agree with you on the evolution from a folded dipole. Wonder
what this design does for gain and F/B. How do check an N connector to
see if you put it together right? Draw any blood lately?

Jimmie

Tesla is not applicable here, an antenna is not a cathode and does not
act like one. Neither is it made of a material that is cathodic at room
temperature.

So where else does it say the current is asymmetrical?

There sure is.  It is typical to see 20dB or so loss when you rotate a
dipole receiving from a vertical ground plane CB antenna from vertical
to horizontal.

 From a car it may not be truly vertical because of the body, but it is
still easy to detect.

Field emission works at each temperature and each material. It is voltage and temperature dependent. Also: "How would the ideal field emitter look like? It should be very long and very thin, made of conductive material with high mechanical strength, be robust, and cheap and easy to process."

>
> So where else does it say the current is asymmetrical?

The emission current from AC lines is. But there the electrons flow to ground. In the lines no open circuit.
In open circuit the voltage is doubled (at least) at the end. If some electrons jump off than the suction voltage is lower. If an antenna radiate the VSWR is low = some electrons do not come back.

In the giant Warsaw dipole was: "In the lower half of the mast, there was a vertical steel tube, attached to the mast's outer structure with large insulators. This tube was grounded at the bottom, and connected electrically to the mast structure at half the total height. This technique works by applying a DC ground at a point of minimum radiofrequency voltage, conducting static charge to ground without diminishing the radio energy. Static electrical charge can build up to high values, even at times of no thunderstorm activity, when such tall structures are insulated from ground.

Guess why the static charge is build up?

The transmmiting "cold catode" is thin and long. It radiate the alternate
electric field perpendicular to its length. Receiving antenna also have the
best direction to collect electrons.

Polarisation is linear, circular, eleptical. Could you produce it by
rotation of monopole?

if there is any breeze: http://en.wikipedia.org/wiki/Triboelectric_effect

or just the clear air electric field: "In fine weather, the potential
increases with altitude at the rate, according to some writers, of
about 30 volts per foot (100 V/m).[3]"
from http://en.wikipedia.org/wiki/Atmospheric_electricity

you can create any direction of linear polarization by rotating a
monopole.

I did something like that over a decade ago under
A constant impedance antenna system
patent application.
What I did was to capacity couple a dipole arrangement
which I placed very close to a antenna array to get a
constant impedance. The final set up comprises then of two occillators. This
coupling method was picked up by a lot of people
because of its attribute of removing noise via
capacitive coupling. Basically the connecting impedance
point travelled along the length of the feed dipole
which also provided a broader bandwidth with a stable
impedance.

"picked up by a lot of people because of its attribute of removing noise"

Hmm, never heard of it. If it's now effectively spread across the antenna and amateur radio world, pray tell, how does it work? Be specific, give examples.

Bet you can't.

Because never prove anything, ever. No examples with numerical values available. Well, except that weird piece of crap yagi-ish thing you once published here. The "pickup-sticks yagi" Not a particularly good antenna performance wise. Ok, lousy.

from http://en.wikipedia.org/wiki/Atmospheric_electricity

You invented a new power plant. But what voltage will be there in fine
weather? In conductor must be the same.  Will it be like at bottom or as at
the top or in the middle?

The sentence "when such tall structures are insulated from ground" is wrong.
Should be: "when such  dipole works".
S*

try it and see... tie a wire to a kite and fly it up nice and high and
measure the dc voltage to ground.  you can also draw current from it.
many years ago i built a motor that was powered by only a wire
sticking up about 20' in the clear air... very interesting free
power!  but very dangerous near thunderstorm!

I've found either an error in the manual or a defective part.

In the assembly instructions at Task I, step 6, the instructions say

"Insert AV-640 Coil Assembly (LI) 4 inches (10cm) into tubing section
BD."

However, LI can only be inserted 3 inches into BD before butting up
against the smaller diameter tube nested inside of BD.

The overall length of BD is 75" as documented, and the smaller internal
tube sticks out the far end 3".

How did yours go together?

I imagine that weather resistance is probably the biggest. Marine
fiberglass antennas are designed to stand up to long-term exposure to
salt spray, and salt air.

Anywhere around the coast, salt in the air will eat aluminum antennas
for lunch. Unless you're very careful to have a mechanically-strong
junction between sections, with some sort of oxygen-and-moisture-excluding goop or grease, you'll end up with serious deterioration
of the metal, and a loss of conductivity between sections.

Just for the record, my question is in regards to the use of such antennas for fixed mobile use on an RV, not for permanent mount.

It is all relative!

I have had my problems along the way but it is the best for me that I have found.

If I compile a program without flipping the appropriate switch in Internet Security it promptly deletes the exe because it does not know it!

It was a pain at first, but now I like it. The big problem is the cavelier manner in which Microsoft software is generated.

Hi Bert,

Probably not, but what is on either side of this "short run" that
loads this run with stress?

Is this a vertical run, or horizontal run?

In textbooks are theories with math. Faraday described an ideas.
His idea without an aether and with the electrons seems to be correct.

The rest of my antenna :-) About 25 feet of more aluminum.

It's actually a Hy-Gain AV-640, and the base tube is made of two nested pieces of .058" tubing, but it's only a foot long, and I'm considering some mounting options that would require a longer section that I'd have to make out of stuff I can buy easily.

> Is this a vertical run, or horizontal run?

It's vertical.

it may seem to be to you, but it isn't.  look at maxwell's equations,
there is no need for free charge for propagating waves.

Hi Bert,

So it is at the point of maximum leverage - something to consider. As it is vertical, then wind forces will be magnified at this point. However, it seems you are doubling the length of what would have been there anyway.

It still seems robust.

Yes, I have. The one I constructed was for the 70 cm band. I have misplaced the frequency/impedance data I took, but I remember that it compared closely with EZNEC. I did not try to measure the pattern, but I did not notice any dead spots when receiving.

The only thing I don't like is that it is more time-consuming to tune because you can't just chop off the end like you can with the unfolded one.

John KD5YI

Hi Bert, I had a similar issue, filled the center of the tubing with
hardwood dowl. The rod I used was for a curtain or closet. I survived
a hurricane and a tornado that took off a good part of my roof. Not
only does it add strength but it keeps the aluminum from collapsing.

It would depend on how you did the nesting.  If there's an
interference fit, then it's pretty much one piece of metal.
If it's not, and they can bend independently, you need to figure out
how the loads distribute between the pieces.

Changes followed by "|".

The rec.radio.info newsgroup, first established in 1993, has been recently revived by an active moderation team. We are currently seeking suitable information, FAQ, and bulletin articles from the entire rec.radio.* newsgroup hierarchy for simultaneous cross-posting to our newsgroup.

We are seeking a replacement maintainer for the following information bulletin formerly posted to rec.radio.amateur.* (and currently archived at http://www.faqs.org/faqs/radio/personal-intro/):

radio/personal-intro
Subject: Guide to the rec.radio Newsgroups
Maintainer: jeffreyh@Hawaii.Edu (Jeffrey Herman)
Last Posted: 9 Nov 2001 06:18:17 GMT
Posting-Frequency: 15th of each month

One significant omission, requiring immediate updates, for this article |

```
is that it does not mention newer amateur radio newsgroups created since      |
it was written, including:                                                    |

 rec.radio.amateur.antenna                                                    |
 rec.radio.amateur.boatanchors                                                |
 rec.radio.amateur.dx                                                         |
 rec.radio.amateur.equipment                                                  |

In Heaviside's model waves are polarised. It means that the waves are
transversal (rotational vibrations). The medium is a solid dielectric.

In Faraday model the two or more sources of pressure waves produce effect
equivalent to the transverse waves.
In Faraday's electrons no transverse waves. Are such in wires?

as long as you continue to live in the 1800's you will never learn the
truth.

I plan to relocate our entertainment system to the basement. At the same time I plan to run cable to the attic for TV and Radio. I would like some advice on what type of cable to run and what types of Antennas would work best from an attic.

Do I need to go buy a radio antenna, or is it just as simple to construct one ?

Thanks'

Just and AM / FM receiver.

I was considering:
2x cat5+ UTP
1x 75 coax for TV
1x 50 coax for FM
AM ??

>

Not necessarily.. you can use something that has a lateral member to put
the antenna at the corner of the car. Or have a pivot to allow you to
swing it out of the way.

As far as the losses go.. just put the base of the antenna (feedpoint)
up higher (mount the antenna on a stalk, as it were). You WANT the
current in the stalk to couple to the car body. The losses in a few
feet of wire to connect the ground aren't a big deal (after all, the
antenna itself is just a piece of wire, and the losses in that are
presumably acceptable)

One way to think of a mobile antenna is as a dipole with a wire on one
side and a very odd shaped ball of wire on the other.

The real thing on the whole grounding thing is to make sure that all the
pieces of the car are grounded together, and that your antenna "ground"
is connected to a big piece of metal. Bumpers, for instance, are often
electrically isolated from the rest of the car by the shock absorbing
mounts.

I've done a variety of schemes like that. A removable bike rack that straps to the trunk lid works fairly well.

I've also built something that clamps onto the towing/tie-down lug. That works pretty well if the lug is in the correct orientation.

A light duty trailer receiver works really well, and when you pull the antenna off, it's very inconspicuous. I did something like this by just bolting a piece of 1x1" square tubing to the bottom of the spare tire well to make a sort of receiver. The antenna mount slides in and it's held in with a couple of removable hitch pins.

pictures (although not very good on the detail you're looking for)

you can normally use the same antenna for TV and FM, and i think most
FM receivers are 75 or 300 ohm inputs anyway.  if you really want a
separate one for FM there are simple cheap parallel wire dipoles that
often come with receivers you can just tack up on the wall.  AM
receivers probably won't care if you use 50 or 75 ohm, just run a loop
of wire around the attic as far from power lines as you can and that
should be fine.

So I end up with 2 coax cables:
1st coax for TV/FM with an antenna in the attic.
    What about a signal amp ?  do they really help ?
2nd coax for AM, loop around the attic  (how big is too big and should
it be parallel or horizontal to the ground ?)

Can I use splitters for multiple receivers, or will this degrade the
signal too much ?

using splitters or preamps depends on how strong the signals you want
to get already are.  if they are strong enough then you can use
splitters without any problem, if they are too weak you may need a
preamp to boost them before splitting.

you can't make an AM loop too big or orient it enough to make any
difference inside your house, just run it around what is easy to reach
and don't worry about it.

>
> As far as the losses go.. just put the base of the antenna (feedpoint) up higher (mount the antenna on a stalk, as it were). You WANT the current in the stalk to couple to the car body. The losses in a few feet of wire to connect the ground aren't a big deal (after all, the antenna itself is just a piece of wire, and the losses in that are presumably acceptable)

It will still be fairly lame compared to the whip mounted on the body of the vehicle. It's not that ground wires are lossy, the biggest problem is the lack of real metal under the base of the antenna.
Heck, I once mounted one on a piece of stout angle iron which was on top of the bed right behind the back cab window of the truck. I had extra strap grounding the angle iron to the bed of the truck, and the whole truck is bonded together.
The antenna was lame. :(I could tell the difference the first time I use it. When I moved over to the top of the utility bed toolbox, it came back alive as normal.
He could try it, but I wouldn't be expecting too good of results. But.. I am spoiled on using good mount locations, so I am admittedly picky. :/

>
> One way to think of a mobile antenna is as a dipole with a wire on one side and a very odd shaped ball of wire on the other.

This is sort of true, but not totally.. It's still going to act more like a vertical on a poor ground, than a perverted dipole. One reason I know this is because no matter what I mount my whip on, it's resonant frequency never changes much at all.

If it acted more like a dipole, even small changes in vehicle size and mount location would drastically detune the antenna to the point it would have to be retuned a bit. But I've never seen this to be the case with mine. No matter where on the truck I mount it, or even if I slap it on a totally different small car, the antenna tunes the same frequency. That tells me, it's actually much more like a vertical with varying qualities of ground, than a dipole with changing lengths on one side.

I know many claim this is the case, including Roy and a few others that are quite knowledgeable, but I don't totally buy it judging from my experiences.

Even when I mounted the antenna on the lame performing angle iron, it tuned the same place. It just didn't radiate worth a hoot. When I moved it to the toolbox with decent metal under the whip, it tuned the same place, but it radiated much better. One of my trucks has the whip mounted on the side of the cab, not much lower than the roof line. It's the best performer out of all the mounts I've tried. The base is high up, and the antenna is tall. So needless to say I'm fairly spoiled. :/

>

Nothing wrong with that advice, but I think it's most important to have that big piece of metal under the whip. It's not going to do much good if it's a few feet away and connected by wires, or even thick strap. I've found this out the hard way.. :(But again, I am picky.. And spoiled.
:/

For a Smith Chart which allows any Zo you wish, try:

http://www.fritz.dellsperger.net/PartInterests.htm

I love this chart. I used the free version for years.

Cheers,
John

Yes and no. I am an ignorant but I am here to learn.

It seems to me that Faraday model fits to todays radio. Why not?

because it is wrong?  at least the stuff that you quote is.  faraday
did make a contribution to maxwell's equations, but not anything that
required an aether or free electrons flying around.

that's true. i used to have a screwdriver that was a BITCH to get
matched because of the grounding

You seem to be resisting learning from those who know much better than you. I would suggest you stop resisting, start listening and begin learning.

I hate to be pessimistic, but I doubt you will do even 1 of the 3 suggestions.

tom

Asking questions is not resisting. Two years ago Richard C. wrote:

"Actually you have mixed up two different characteristics. Polarity
and polarization are NOT the same thing. With RF radiation, the wave
is constantly changing polarity (that is why the source of RF is
called alternating current), but within the "line of sight" of the
antenna, the polarization for a dipole is defined by its angle to the
earth as viewed by the observer.

If you see an horizontal dipole, it produces alternating polarities of
waves with horizontal polarization. If you see a vertical dipole, it
produces alternating polarities of waves with vertical polarization.

RF energy is ALWAYS changing polarity."

Can a monopole produce "polarisation"?

I recently bought a great new antenna with 100 mile range radius.

Hello Bert,

If I understand you well, the current tube is a nested construction (one foot). Considering the overall length of the antenna (25 feet), the bending moment will slightly increase when changing from 1 to about 2 feet.

If you believe that there will be more clearance between the two tubes (w.r.t. the current nested tubes), you may fill the clearance with epoxy resin. This will reduce the risk on buckling significantly.

Best regards,

Wim

PolariZation.

A vertical monopole is vertically polarized when viewed in isolation
of other reflectors at a distance of many, many wavelengths.

I presume "great" was meant to be ironic. Are you asking how to get a
refund? Simple antennas have ranges into the thousands of miles.

I find it sad that amateur radio operators feel the need to loose respect for each other just because these newsgroups are *mainly* accessed from the internet.

Mention the "internet" aspect of these forums and suddenly people feel it's ok to bash, curse, and make all out war with each other.

I should remind all that these newsgroups are also fed in and out of packet radio BBS stations and read and replied to over RF in nearly all countries utilizing packet BBS's.

Your name calling, cursing and war-ing all go out over the air ways and do nothing to foster and promote the art of amateur radio.

The 'art' of amateur radio?

A bunch of fat, sweaty, socially-maladjusted losers, sitting by themselves in their shacks for hours on end, grousing about how this newfangled interwebnet will never be as useful as the radio they built back in '63 and masturbating furtively over memories of Field Days past?

That's the reality of amateur radio today. As long as there are people like you who continue seeking to use yesterday's technology to solve yesterday's problems, I'll expect more whining along the lines of the above.

Let me spell it out for you: USENET - much like the rest of the Internet - was never intended for transport over amateur radio frequencies. That you (and others) do this is one thing, but pissing and moaning about the content of a medium not covered by FCC or international regulations is, frankly, idiotic on your behalf. Don't like it? Send your own damn traffic out over the airwaves. But don't expect the rest of us to kowtow to your demands.

People wonder why amateur radio is dying. You, my good man, exemplify one reason for that *exceptionally* well.

And, for the benefit of the masses who read USENET via their Icoms, Yaesus, or Kenwoods: FUCK SHIT PISS CUNT DICK BALLS ASS TITS BONER.

73s,

- J.

That was almost a sentence. Keep trying; perhaps you'll get it right eventually!

Anyway, I now see why you're so deeply concerned about dirty words on the Internet making it out over the airwaves:

http://groups.yahoo.com/group/BPQ32/message/3118 (May 1, 2010)
http://www.db0anf.de/app/bbs/messages/show-1239_KG6BAJ (May 3, 2010)

As I see it, this leaves you with two options:

- Fix your filters so that they actually work.

- Stop sending USENET posts over the airwaves.

There you go; problem solved.

Also, I'm pretty sure that I forgot to say 'dildo' in my original reply to you. I'd hate to think that you missed out on my use of the word 'dildo', so here's a use of the word 'dildo' just for you:

DILDO.

Some good points. However, IMHO amateur radio should have no direct
connection to the internet.

Why? These people don't have internet access?

>
> Your name calling, cursing and war-ing all go out over the air ways and do
> nothing to foster and promote the art of amateur radio.

If that is the case, you are at fault for broadcasting
such content. It's no fault of the internet.
The internet is not amateur radio, and was never
intended to be.
I know myself, I would never broadcast usenet
content over amateur radio, even if it were all
squeaky clean and politically correct.

Packet? People actually still use it?   :/
I never saw the attraction myself, but that's just me.
Packet bored me to unprecedented levels of stupor,
even when it was actually a fairly modern mode of
communication.
But even if I used it, I would not transmit internet
content, unless I was relaying important ARRL bulletins,
emergency health and welfare information, etc.
Transmitting usenet? Never.. Ever.. Nada, Zilch..

Some do. Not all. Not even a significant percentage of all. Myself excepted.

> I should remind all that these newsgroups are also fed in and out of packet
> radio BBS stations and read and replied to over RF in nearly all countries
> utilizing packet BBS's.

That is possibly illegal considering you are seemingly not vetting the content. That would be the equivalent of transmitting porn videos on 70cm ATV and blaming the people who produced the tape/DVD. Moron. I feel justified on that remark.

> Your name calling, cursing and war-ing all go out over the air ways and do
> nothing to foster and promote the art of amateur radio.

Then don't read it, don't transmit it via packet, print it and post it on telephone poles on the corner, forward it to coworkers......

Get it yet?

A 100-mile radius? HOLY SHIT, THAT'S A 200-MILE DIAMETER!

See what I did there? Doubled your range for you FOR FREE.

BUT WAIT, THERE'S *MORE*!

Did I say 200 miles? I must've been coming down from PCP when I did,
because I *really* meant THREE HUNDRED AND TWENTY KILOMETRES! That's a
number that's 160% *larger* than 200!

```
Your numbers are now three-point-two times bigger than they were when
you started.  No need to thank me; just take a shower and we'll call it
even.

Has anyone used or tried an antenna like this ?

http://www.g0ksc.co.uk/intro-lfa.html

Called a loop fed yagi. It is mostly a VHF beam where the driven element is a loop. The loop is flat with the boom so it looks similar to an extra element with the ends joined.

There is an example of a 5 element 50 mhz beam. It takes about the same

ammount of aluminum to make a 6 element beam. Would this antenna be more of
an advantage over a 6 element beam of say the K1FO type ?

Hmmm. It's somewhat similar in philosophy to the "quagi" (Yagi-type directors, with a quad-loop driver and reflector, but I think it's even closer to being a Yagi with a folded-dipole driven element (you can think of a folded-dipole DE as being a very-wide-and-shallow loop).

You can follow a progression of these designs, from a Quagi (which uses a square loop DE), to this "loop-fed Yagi", to a standard Yagi fed with a folded dipole driven element, and then to the WA5VJB "Cheap Yagi" with its half-folded dipole driven element. All of these use the folding or looping of the driven element to raise the feedpoint impedance, which would otherwise usually be well below 50 ohms. The shape of the driven element controls the type of impedance transformation you get.

Dear Mikek: Thank you for your response. Knowing goals is important.

A great deal could be learned by using an antenna modeling computer program such as EZNEC.

Note that my estimate of the antenna's Z is calculated with one assumption (some loss in the series inductor) and that its calculations equate 55 + j0 to the impedance of the inductor, capacitor and antenna. Some of the calculations I have seen seem to assume that one has applied 55 ohms and then look backwards from the antenna.

Place my estimate of 159 -j526 in parallel with -j717 and then add (the series) 3 + j310. You should fine the result to be
55.053 -j 0.0711 which is close to 55.

Maximizing the sensitivity of a semiconductor diode detector is probably done empirically because of the difficulty of finding an appropriate model for the non-linear detector. Expect that the apparent answer will be amplitude dependent.

Do report you findings. Regards, Mac

From what I have read it seems very high, could I have 130 ohms of ground loss?
I don't think so.

I'll be looking into the ground, I think it is just a 6 foot rod, I put it in years ago.
I'll add FWIW, I connected the AC ground from a receptacle and it made zero change.

> However, the idea that even such a simple an antenna can be modeled as an
> R and C over the AM broadcast frequency range seems unlikely.

Ya, that's not the plan, I'll check it every 100 khz and make a graph, with R and C.

> An instrument such as the AIM4170C would provide Z with greater confidence
> and do so at each frequency of interest. However, in the broadcast band
> it is not clear that such a set of impedances can be used for something
> useful. What is the actual goal?

I put the antenna up for multiple use, but to start, I want to use it with a crystal radio,
the measurements may help me figure out the series cap (range) needed to

make an
R match to the tank circuit over the band.
And it's a project that forces me learn some math.
Thanks, Mikek

Hi J. C.
If your interested in the diode characterists Ben Tongue has done a lot of
crystal radio work.
http://www.bentongue.com/xtalset/xtalset.html
Articles 6, 7, 8, 9 , 10, 15A, 16, 17A, 27 and 28 are all about detector
diodes and there characteristics.
Thanks, Mikek

On many cars these days, there is a plastic cover at the end of the roof
rack that covers a bolt that holds the rack onto the car.  A ring lug
under the bolt and a black powerpole connector glued into a notch cut in
that plastic cover might give a really nice connection to the metal roof.

Ed,

The Smith Charts with R=1 in the center are normalized charts. If you have 50 ohm coaxial cable, just multiply the numbers by 50. You may occasionally use 75 ohm cable. While you can buy charts with R=75 in the center, all you have to do with a normalized chart is to multiply the values by 75. I doubt if you can even buy charts specifically for 93 ohm (RG-62) cable, 300 ohm twinlead, or 450 and 440 ohm "window" line.

I always compute the reflection coefficient from a complex load before I calculate the VSWR.

? (Greek capital letter Gamma) = (Zmeas - Zline)/(Zmeas + Zline)

We usually think that we can replace the line impedance with 50 + j0, but as my friend Tom, K7ITM, often points out, so-called 50 ohm cable no longer has a purely resistive characteristic impedance at low frequencies. So we need to calculate the reflection coefficient as a complex number. Once we have this, we need to determine the magnitude of the reflection coefficient.

? (Greek lower case rho) = |?|

= sqrt(Real*Real + Imag*Imag)

Once we know the magnitude of the reflection coefficient, which is always less than or equal to unity, the voltage standing wave ratio is simply

VSWR = (1 + ?)/(1 - ?)

If you have Windoze, all of these calculations are easily done in Excel. You may have to install the Analysis Toolpack to get Excel to handle complex numbers.

I strongly suggest that you continue to use Smith charts. The first large program for my TI-59 calculator nearly forty years ago was an electronic Smith chart. It was handy. but I continued to use Smith charts because they offer graphically significant insight into what happens along the length of a transmission line. Additionally, they help you catch mistakes.

73, Barry WA4VZQ

Postscript: I used rich text format solely because I could use Greek letters. Gamma and rho are almost universally used to represent the complex reflection coefficient and its magnitude respectively in engineering publications.

I don't know what a Honda element looks like but if it has a hatch back
or trunk lid I can show you a way to mount an antenna that will work -
where can I send you pictures?

Hello, and I believe some clarification is needed here. First, for most ham radio applications we can assume a real characteristic impedance for the transmission line (e.g. Zo = Ro = 50 ohms). The only time this leads to large errors when calculating the line-transformed load impedance (e.g. an antenna at a given frequency) occurs when the VSWR of the load is greater than 10 or 20. (This was pointed out in a 1953 AIEE paper by W. W. Macalpine.)

However, just because the reference impedance, Zo, is assumed to be real doesn't mean that the reflection coefficient has to be real. Sincerely, and 73s from N4GGO,

Thanks for commenting, James.

I decided to calculate the characteristic impedance of Times Microwave =
LMR-240 cable at several frequencies just to see. This is basically a =
foamed dielectric version of RG-58 and I had the data handy.

The equation for characteristic impedance is:

```
    Zo =3D sqrt[ (R + j*w*L) / (G + j*w*C) ]
```

```
where: R =3D distributed series resistance, Ohms/meter
       L =3D distributed series inductance, Henries/meter
       G =3D distributed shunt conductance, Siemens/meter
       C =3D distributed shunt capacitance, Farads/meter
       w =3D radian frequency, 2*Pi*f, radians/second.
```

For LMR-240, Times gives:

Inner Conductor Solid BC 0.056 in (1.42 mm)
Dielectric Foam Polyethylene 0.150 in (3.81 mm)
Outer Conductor Aluminum Tape 0.155 in (3.94 mm)
Overall Braid Tinned Copper 0.178 in (4.52 mm)

Velocity of Propagation 84%
Dielectric Constant NA 1.42
Time Delay nS/ft (nS/m) 1.21 (3.97)
Impedance ohms 50
Capacitance pF/ft (pF/m) 24.2 (79.4)
Inductance uH/ft (uH/m) 0.060 (0.20)
Shielding Effectiveness dB >90
DC Resistance
Inner Conductor ohms/1000ft (/km) 3.2 (10.5)
Outer Conductor ohms/1000ft (/km) 3.89 (12.8)
Voltage Withstand Volts DC 1500
Jacket Spark Volts RMS 5000
Peak Power kW 5.6

So with this data, assuming the resistance is constant with frequency =
(reasonable considering the skin depth), we get:

```
    R =3D (10.5 + 12.8)ohms/1E3-meters =3D 0.0233 ohm/meter
    L =3D 0.20 uH/meter =3D 2E-7 Henry/meter
    C =3D 79.4 pF/meter =3D 7.94E=3D11 Farad/meter

To get G, we know that the dielectric is foamed polyethylene with a =
resistivity of 1E16 ohm-cm, or 1E14 Ohm-meter.  The equation for =
conductance in the concentric configuration of coaxial cable is:

    G =3D G =3D 2*Pi*Sigma/ln(B/A) =3D 6.283E-14/ln(3.81/1.42) =3D =
6.366E-14 Siemans/meter

At this point, I used Excel 2003 with the Analysis Toolpack to do the =
caculations with complex numbers.  While Excel does the calculations =
without difficulty, Microsoft never thought about formatting complex =
numbers, so the following table is edited from Excel by hand. :-(   =
apologize for any transcription errors.

Frequency, Hz    Characteristic Impedance, Ohms        Magnitude        =
Phase, degrees
  1.000E00           4832.837 - j4831.960               6834.044         =
-44.4994
  1.000E01           1528.565 - j1527.717               2161.115         =
-44.9842
  1.000E02            484.545 - j481.932                 683.409         =
-44.8455
  1.000E03            156.989 - j148.750                 216.284         =
-43.4564
  1.000E04             62.551 -  j37.333                  72.845         =
-30.8304
  1.000E05             50.402 -   j4.633                  50.614         =
- 5.2521
  1.000E06             50.191 -   j0.465                  50.193         =
- 0.5311
  1.000E07             50.189 -   j0.001                  50.187         =
- 0.0531

So as we go increasingly below one MegaHertz, the characteristic =
impedance of the cable increases to above 50 ohms and it becomes =
increasingly capacitive.  If the FCC grants hams a band in the LF =
region, we might have to consider this.  But then, our cables will be =
very short in terms of wavelength.

        73, Dr. Barry L. Ornitz     WA4VZQ

They do the reverse of this in AM broadcast antenna matching
networks (doghouses) where the object is NOT to have a variable
capacitor.  A fixed, high-reactance capacitor is placed in series
with a 'tappable' inductor and the capacitor is 'tuned' by adjusting
the tap on the inductor.  Again, works well at one frequency,
but not over an octave bandwidth.... K7JEB

The OP's arrangement works well for impedance matching and is suitable
for tuning a circuit to resonance. I dont believe the circuit he
described would be much different from the resonant circuit in a
Colpitts osc.

I am considering this antenna for Grundig Satellit 750, link below.

http://universal-radio.com/catalog/sw_ant/3377.html my first question is about the effectiveness of this antenna in a limited space on patio of about 15 feet by 15 feet, next to a 2-story building. I would raise the antenna center to about 10 feet and then run each of the 40-foot wings in zigzags on the sides. Later, I might move to a larger place and have full space for the antenna. I do not want to buy an antenna for limited space now if this antenna could be made as effective for the limited space as an antenna designed for smaller space.

the second question is about durability, is it solid construction to last for years?

the third question is about any extra hardware needed. My Grundig radio has a female BNC socket 50-ohm. This antenna comes with coax cable RG-8X and PL-259. This means I need an adapter from PL-259 to BNC. Will this adapter create any noise? Do I need any additional hardware to make it work better, like a preamp?

>
> =A0 =A0 =A0 =A0 73, Dr. Barry L. Ornitz =A0 =A0 WA4VZQ

Barry's assumption of resistance being the same as the DC resistance
and independent of frequency will make the characteristic impedance
look closer to resistive than it actually is, at frequencies where
skin depth is small compared with conductor thickness.  Since in
copper, skin depth at 1MHz is only about 2.6 mils (and is inversely
proportional to the square root of the frequency), the resistance of
that particular line's conductors at 1MHz will be considerably higher
than the DC resistance.

Dare I mention that when the line impedance is reactive, you can get
reflection coefficients with magnitude greater than unity?  Seems like
every time that comes up here, someone gets their knickers in a knot
about it.  Reflection coefficient =3D rho =3D (Z-Zo)/(Z+Zo), so if Z (the
load impedance) is a pure inductance, say +j50 ohms, and the line
impedance is (from Barry's chart) 50.4-j4.63 ohms, then rho =3D
-0.0134+j1.096, and |rho| =3D 1.096.  But to calm your nerves, calculate
what the impedance is looking into any length of that line you wish,
terminated that way, and you'll see that the impedance never has a
negative real part.

Cheers,
Tom

I own this kind of antenna. Any opinion about this product?
Is the installation difficult?
Many thanks

Looks like a decent antenna for your purposes.

This will work fine.

If anything would improve your situation, it would be raising it
higher.

>the second question is about durability, is it solid construction to
>last for years?

Dunno. At the prices shown, they are within ballpark for the
complexity offered. Wire lasts a long time. You could certainly pay
more, much more, and obtain no better results on your radio, and for
no longer life in the air.

Not in the least.

>Do I need any additional hardware to make it
>work better, like a preamp?

Get a cheap antenna tuner. Look around for Ham radio antenna tuners
that do not have metering (you don't need, and couldn't use it
anyway). If you come across one that has metering, and is cheap
enough, buy it.

You can also build your own tuner if you are hobby inclined. It is
simple enough, requires few skills, tools (a soldering iron) and parts

(two multiposition switchs, make your own coil, find two variable
capacitors) in a box.

news:PapiBow.78bfa58@radiobanter.com...

I am considering this antenna for Grundig Satellit 750, link below.=20

http://universal-radio.com/catalog/sw_ant/3377.html

my first question is about the effectiveness of this antenna in a
limited space on patio of about 15 feet by 15 feet, next to a 2-story
building. I would raise the antenna center to about 10 feet and then =
run
each of the 40-foot wings in zigzags on the sides. Later, I might move
to a larger place and have full space for the antenna. I do not want =
to
buy an antenna for limited space now if this antenna could be made as
effective for the limited space as an antenna designed for smaller
space.=20

the second question is about durability, is it solid construction to
last for years?

the third question is about any extra hardware needed. My Grundig =
radio
has a female BNC socket 50-ohm. This antenna comes with coax cable =
RG-8X
and PL-259. This means I need an adapter from PL-259 to BNC. Will this
adapter create any noise? Do I need any additional hardware to make it
work better, like a preamp?

--=20
PapiBow

I just can't see paying over $ 150 for a bunch of wire to use as a =
receiving antenna. Think I would just put up a center insulator and as =
much wire as I could in the space you have. Also do a search for a =
Windom antenna. You probably will get the same results for a lot less =
money.

Yesterday, while repairing my antenna, something came to my mind I had never focused on before.

Let us consider a bipole, that is a "black box" having TWO terminals and including plain passive elements only (like capacitors, inductors, ... , no diodes or other special devices), arranged the way you prefer, it does not matter.

In my mind it was quite clear that, when fitting such a bipole into a circuit, the sense makes no difference, i.e. one can reverse the two terminals with no consequence. As a matter of fact, the bipole has an equivalent impedance that remains the same independently of the way it is put in the circuit.

Yesterday a case occurred to me in which this is not actually true.

Instead of directly telling which it is, just for fun I wonder whether anyone
can figure out a case in which a bipole may not be reversed without
consequences. Not difficult, but it anyway requires some thinking.

Although probably unnecessary, let me recall that a filter is typically a
THREE-terminal device (IN, OUT, GROUND), not a TWO-terminal one.

Hello Tony,

The answer may be in your own text (the ground issue). There may be a third path via ground (capacitive coupling).

You can add a very good common mode choke at the input terminal of you bipole. In that case the path via ground is blocked.

Try a very simple bipole: metallic case connected to terminal 1, terminal 2 connected to nothing. When the center conductor of your source is connected to terminal 1, you have the ground path.

The effect of reverse connection will be less when you use a very small battery powered source that is completely floating. Measuring data you can get out of it via optical link...

Best regards,

Wim

Hi Wim,

I acknowledege that your example leads to an asymmetric bipole, that one cannot reverse it without consequences.

However, in the case which occurred to me, there is no need to assume the existence of a third path via ground for justifying the asymmetry. Actually the asimmetry remains even if the bipole would be in free space!

Forgive me if I do not immediately reveal my case, but I would like to see if there are some more guesses before closing the issue.

as long as it is ONLY 2 ports, has ONLY passive linear components, AND is small enough to be considered a lumped element, then you can always reverse the terminals and not know the difference. The most frequently violated condition is the last one, put in a piece of coax with that is long enough to be measured at the highest frequency you will use and all bets are off.

An electrolytic capacitor acts differently if reverse biased. The results
are usually bad. It does qualify as two leaded, passive and linear when used
properly.

On second glance at the page, I noticed my eye was drawn to the cost of the downlead, not the antenna. Yes, $150 + another $30 - $40 is a lot of money to spend, if you can "do it yourself." Most can do it themselves - wanting to is another matter.

Hi Antonio,

This would fall into the area of a hidden variable (a ghost terminal, so-to-speak) and is called Common Mode. This occurs in the situation that includes the proximity of ground which is often neglected as an influence.

The dipole could be unbalanced forcing currents to be out of balance. This is notorious with cabled down leads which preserves the sense of two terminals, but the imbalance with ground forces a third terminal into the reality of implementation.

If we were to divorce ground from this (free space) and simply looked at the two lead impedance at the drive point, then adding a cable will force the same imbalance (albeit to a different degree, as found with the proximity of earth). If the dipole is off-center fed, this will be more profound (even though when it is measured at the feed point, the measurement is immune to pole switching).

Reversing the "polarity" of the cable connection will create a new topology (although the Common Mode will persist with new characteristics).

>Although probably unnecessary, let me recall that a filter is typically a
>THREE-terminal device (IN, OUT, GROUND), not a TWO-terminal one.

Well, even though I have anticipated ground, a filter can easily be a two terminal device without need for ground - being a series component. This two terminal description is quite typical too.

Hi Joe,

The same can be said of a diode. Hence the electrolytic capacitor is non-linear, which violates the premise.

an electrolytic that acts that way is not a linear component.

Changes followed by "|".

After a 30-day public discussion and feedback period to gauge reader opinions in March of 2009:

http://groups.google.com/group/rec.radio.amateur.moderated/browse_thread/thread/d7d337db35f23326

the rec.radio.amateur.moderated Moderation Team has decided to consider amending its charter, and permit limited simultaneous crossposting to rec.radio.amateur.moderated and one other unmoderated amateur-radio-related discussion newsgroup. We are currently trying this on a temporary basis (90 days, through early July 2009), and adopt it permanently if successful.

Approved rec.radio.amateur.* newsgroups are those that are currently listed in the latest version of the "List of Big Eight Newsgroups" which is crossposted monthly to news.announce.newgroups, news.groups, and news.lists.misc.

Approved alt.radio.amateur.* and alt.ham-radio.* newsgroups are those that have been created consistent with the suggestions in "So You Want to Create an Alt Newsgroup" at:

http://www.faqs.org/faqs/alt-creation-guide/

Approved regional hierarchy newsgroups are those that contain either "radio.amateur" or "ham-radio" in their names, including uk.radio.amateur and aus.radio.amateur.misc.

We will make every reasonable effort to keep our list of approved newsgroups up-to-date. In case we have overlooked any, and a submission is rejected in error as a result, the rejected submitter can E-mail us at our administrative contact address (in the signature at the bottom of this article, and the default Reply-To for the rejection message) requesting that it be added, and that the article be approved. We may still choose to reject articles crossposted to any alt.* newsgroup with an inappropriate name, including obscene language, embedded name-calling, or encouragement of unlawful conduct.

Please direct any comments, questions, or criticisms to rec-radio-amateur-moderated-request@panix.com.

To to feed a delta loop with a 1/4 wavellenght coaxial section I used my
MFJ259B following the instruction of the MFJ259b manual (7.1 Testing
Stubs)
To verify the section I have followed other two methods:
1. MFJ259 manual (Testing Stub with help of 50ohm resistor for lowest
SWR)
2. ON4UN method described by Low-Band Dxing Book (Chapter 6,
Quarter-wave matching section)

The measures that I got with each of the three methods are too
different.
By accepting a reasonable differences in the results, which of the three
methods are considered more reliable ?
Ed, IV3TQE

I assume you are trying to configure a 1/4WL 75 ohm piece of coax to interface to your ~100 ohm loop. What I would do is cut it a little longer than 1/4WL with the velocity factor taken into account. Connect it to the antenna and trim for lowest SWR on the MFJ258B. Why bother with an exact 1/4WL when you can trim for lowest SWR using the actual antenna?

I have a circuit I've been working on lately which has a simple series
LC in it, no other connection to the node between the inductor and
capacitor.  It turns out that the order of the inductor and capacitor
makes a big difference in the circuit performance.  I anticipated that
it would, and put them in the intuitively obvious order, only to find
out that it was the wrong order!  A proper model cleared things up
quite nicely.  However, in no way would I call that particular part of
the circuit a "two terminal" network.  The effect is the same as Wim
mentioned.

Cheers,
Tom

As long as it is ONLY 2 ports, has ONLY passive linear components, AND
is small enough to be considered a lumped element, then you can always
reverse the terminals and not know the difference. The most
frequently violated condition is the last one, put in a piece of coax
with that is long enough to be measured at the highest frequency you
will use and all bets are off.

Could you please explain me the meaning of your sentence:

"put in a piece of coax with that is long enough to be measured at the highest
frequency you will use and all bets are off"

as I have difficulties to interpret it due to my non-mother tongue english.

the general case is, if any part of the circuit is more than a small
fraction of a wavelength in size you may be able to detect the
difference between the ports.   one common way to do that is to try to
measure a circuit that has a long piece of coax in it, the results may
be very different when you reverse the terminals.

then there is either something wrong with your components or you have
too much coupling the the surrounding environment... so you really had
a 3 terminal network using the stray capacitance or inductance.

If by "too much" you mean "more than I wanted," you're absolutely
right.  But of course with real components, there is no such thing as
zero coupling to the surrounding environment.  As with all real
circuits, there are tradeoffs:  high coil Q results in a large coil,
which in turn results in more capacitance to the shield than a smaller
low-Q coil would have.  The shield is required for other reasons...

> ... so you really had
> a 3 terminal network using the stray capacitance or inductance.

Exactly.  Just what I said:  the effect is the same as Wim mentioned.

Cheers,
Tom

This can be neutralized employing a "Wagner Earth." For inductors,
there is the Modified Owen method.

Basically, problems of this sort have been handled with driven shields
(a variant of the Wagner Earth/Ground). This exactly century-old
topic ("Wagner Earth") is rarely discussed outside of precision
measurement or very high voltage handling circuits, however.

You have pinpointed the correct issue: lumped elements.

The story began when, a few days ago, I was going to replace a trap of my HF yagi. Not to make mistakes, I consulted the antenna assembly manual where I found a big banner: do not invert traps otherwise the antenna will not work.

So, I thought, this is a case in which a bipole cannot be inverted.

This is clearly due to the fact that the external body of the trap (an aluminuim can about 2 feet long), which contains two coils resonated at different frequencies by means of built-in capacitors, is effectively part of the antenna radiating element. So, the trap is a bipole not only comprising lumped elements, and that is the reason why it cannot be inverted.

Tom,

the story began when, a few days ago, I was going to replace a trap of my HF yagi. Not to make mistakes, I consulted the antenna assembly manual where I found a big banner: do not invert traps otherwise the antenna will not work.

So, I thought, this is a case in which a bipole cannot be inverted.

This is clearly due to the fact that the external body of the trap (an aluminuim can about 2 feet long), which contains two coils resonated at different frequencies by means of built-in capacitors, is effectively part of the antenna radiating element. So, the trap is a bipole not only comprising lumped elements, and that is the reason why it cannot be inverted.

So, as K1TTT has pointed out, a bipole can be inverted without consequences only if it has only 2 ports, has only passive linear components, and is small enough to be considered a lumped element.

Hello Tony,

So it isn't a bipole.

The tube containing the trap is a (short) common mode transmission
line that has effect on its environment (like a metal case with its
capacitive effect on ground). The trap inside the metal tube is in
series with the end of the short transmission line.

The ground in this case is the boundary where the near field is no
longer dominant w.r.t. to the radiating field. Think of a circular
ground at 0.16lambda from the structure. So one end of your bipole
has more ground to this virtual ground and is therefore a 3-pole
device.

For the limitation on lumped circuit approach, it is not important

whether or not it contributes to the overall radiation of a
structure. When you make a floating ground out of 4 quarter-wave
radials (monopole?), this structure has minor influence on the far
field pattern of the quarter wave (or better half wave) radiator above
it.

Best regards,

Wim

In http://www.padrak.com/ine/FARADAY1.html Faraday wrote:

"The view which I am so bold to put forth considers, therefore, radiation as a kind of species of vibration in the lines of force which are known to connect particles and also masses of matter together. It endeavors to dismiss the aether, but not the vibration. The kind of vibration which, I believe, can alone account for the wonderful, varied, and beautiful phaenomena of polarization, is not the same as that which occurs on the surface of disturbed water, or the waves of sound in gases or liquids, for the vibrations in these cases are direct, or to and from the centre of action, whereas the former are lateral. It seems to me, that the resultant of two or more lines of force is in an apt condition for that action which may be considered as equivalent to a lateral vibration; whereas a uniform medium, like the aether, does not appear apt, or more apt than air or water."

Is your 4 quarter-wave radials (monopole?), the same like Faraday's lines?
Two or more monopoles produces "polarised waves".

Two or more monopoles "is in an apt condition for that action which may be considered as equivalent to a lateral vibration;".

Some textbooks say that Faraday suggested the transverse (angular) wibrations.
Did he?

Hi Antonio,

No, in fact.

You clearly state in the first sentence the reason why.

The external body renders an asymmetry. The two elements it separates are also non-symmetrical (both physically and electrically).

This is NOT a lumped circuit exercise that has gone bad.

HyGain [MFJ] claims 80mph, unguyed. Does anybody have any personal experience to confirm or contradict this?

My somewhat smaller CushCraft R5 has stood unguyed (on a roof tripod) for 20 years.

If I want to guy the 640, I'd have to move the tripod, which means more holes in the roof.

A bipole is symmetrical, obviously the internal circuity of the trap
is not symmetrical  .

Jimmie

A bipole is symmetrical, obviously the internal circuity of the trap is not symmetrical .

Jimmie, that is not the point.

- if the bipole is made of lumped components, then it can be freely reversed without consequences, independently of whether it is symmetrical or asymmetrical

- a trap, which instead contains a distributed element (that is the radiating trap body), can be freely reversed without consequences only if it is symmetrical (which is not my case).

At some frequency, everything becomes a distributed component, it depends on size/lambda ratio and application. Many distributed components can be modelled based on theoretical lumped components (with sufficient accuracy), but a ground for modelling stray capacitance is frequently required.

True lumped component behaviour, in my opinion, only applies to networks with size=3D0.

What do you define as "lumped component"?

I hope you can read what you quoted above and understand it... note
specifically:

> It endeavors to
> dismiss the aether, but not the vibration.

so with this he has decided there is NO aether!

> is not the same as that which occurs on the
> surface of disturbed water, or the waves of sound in gases or liquids,

so all the comparisons to water waves or sound waves are NOT correct!

> equivalent to a lateral vibration

NOT longitudinal!

so by these statements he has said that electromagnetic waves ARE NOT
caused by an aether, and ARE lateral, NOT longitudinal... and CAN NOT
be compared to sound or water vibrations!
```

'True' or theoretical versus 'practical' is a very important distinction that is, or at least was, taught in engineering classes. it is very important to know when you can apply the practical simplifications that allow you to do design work without worrying about insignificant phenomena in the problem domain you are working in... so if i am designing an HF antenna I know that objects below a given size can be safely ignored, but if i'm doing a microwave design i have to take into account much smaller objects.

Ik such words: "I suppose we may compare together the matter of the aether
and ordinary matter (as, for instance, the copper of the wire through which
the electricity is conducted), and consider them as alike in their essential
constitution; i.e. either as both composed of little nuclei, considered in
the abstract as matter"

In your antennas and in the space are free electrons. We do not need a
mystery aether.

>> is not the same as that which occurs on the
>> surface of disturbed water, or the waves of sound in gases or liquids,

>so all the comparisons to water waves or sound waves are NOT correct!

You know that the dipole works like the two loudspeakers.

>> equivalent to a lateral vibration

>NOT longitudinal!

And not traversal. The waves radiated from the two ends of a dipole I call
"coupled".

>so by these statements he has said that electromagnetic waves ARE NOT
caused by an aether, and ARE lateral, NOT longitudinal... and CAN NOT
be compared to sound or water vibrations!

Faraday was great. In the Nature no natural acoustic dipoles. For him was
obvious that must be something equivalent to a lateral vibration.
As you know it is the two or more sources of pressure waves properly phased.

Are electrons jumping off from your transmitting antennas?
In copper and in space are the same "little nuclei, considered in the abstract as matter". Electrons have mass.

Biot-Savart's magnetic whirl is massles.

no, electrons don't jump off my antennas, and there can not be free
electrons in space or they would all repel each other and fly away.
and since they have mass and other detectable properties we would
easily be able to measure them if they were conducting electromagnetic
waves, such a simple thing as speed of the wave would be VERY
different than what we measure now.

As I see it, it has nothing to do with being small enough to be
considered a lumped element.  Instead, it has to do with coupling
between the network elements and the outside world.    Clearly your
trap is coupled to the outside world.  Clearly the series LC in my
example is coupled to its surroundings.  In such cases, you're NOT
dealing with a two-terminal network:  there is a path for current
other than the two terminals.  You can put as many transmission lines
in your network as you wish, and as long as they don't have coupling
to the rest of the universe except through the two closely-spaced
terminals, there will be no difference in behaviour if you reverse the
terminals.  If you can show a valid counter-example, you've proven a
whole lot of textbooks wrong...

I suppose equivalently, if you decouple your measurement from the rest
of the universe, you'll get the same result.  Typical broadband
directional couplers (of the sort used in S-parameter test sets) have
```

good decoupling, to be able to separate excitation from return power.

Cheers,
Tom

```

I had an idea that seems to work.

I like inherently DC-shorted antennas because of an experience I had about 30 years ago with thunderstorms. Using a home-brew quarter-wave vertical on 2 meters, my receiver got completely blocked for about 10 seconds by a lightning stroke a few miles from my location. I was terrified that I had lost the front end of the IC-2AT. Fortunately, I did not, but that experience apparently imprinted on my so-called brain. I know that I could add a shunt inductor across the terminals to prevent this, but I prefer a natural or inherent solution.

The folded vertical unipole is inherently "grounded". (I use quotes here because what I really mean is that the antenna input is DC-connected to the common.) So, I like that antenna. However, its terminal impedance is about 4 times that of a simple ground plane.

Well, I noticed that the terminal impedance of a simple quarter-wave unipole was about 30 or so ohms until the radials are sloped downward at about 45 degrees which raises the terminal impedance to about 50 ohms.

In my case, I needed to lower the terminal impedance (about 120 to 140 ohms) of the folded antenna. Well, what if I sloped the radials *upward* approximately 45 degrees to lower the terminal impedance to about 50 ohms?

It worked, and EZNEC says that the radiation pattern is pretty much like the usual ground plane vertical.

I just thought I would share this info with the group. I also have a configuration for a full-wave loop (inherently at DC common) on 70 cm that has an infinite balun thanks to Walter Maxwell's book Reflections II, page 22-10. How I manage to get the terminal impedance to 50 ohms is interesting, but I will save that for another post.

Cheers,
John KD5YI

Tesla did the electron gun from an antenna. Why yours are different?

>and there can not be free
electrons in space or they would all repel each other and fly away.

They do. The rare plasma is produced by the Sun. After condensation they
come back to stars.

>and since they have mass and other detectable properties we would
easily be able to measure them if they were conducting electromagnetic
waves,

The electron gun produces the catode rays. You are able to measure them. Put
on a glas bottle with the anticatode on the top of CB radio antenna.
Your current meter measures the DC ground current.

>such a simple thing as speed of the wave would be VERY
different than what we measure now.

Speed of the electric waves is and will be the same for ever. Of course for
the same temperature.

Faraday stated that must be: "that action which may be considered as
equivalent to a lateral vibration; "

The two (or more) sources give the same result like mystery TEM.

Are you better than Faraday?

You're right, trimming is the easiest method to matching a delta loop.
Anyway I hope my Analyzer could help me to get 1/2 wave coax and some
sections for a phasing system

Do you need " the action which may be considered as equivalent to a lateral vibration; "?
Or you are fine with TEM?

```

The ones I've used seemed so broad, trimming really didn't
seem to be needed. It's kind of like using a matching device
with a mobile antenna. For most, it will be left at a single
setting, even for a whole band, and any tweaking done will be
at the antenna. I'll usually cut one to the usual length and
throw it up. IE: for 40m, I just cut 22 feet and I'm usually
done with it. They don't seem that critical.
I have an old puter program that would calculate those for most
any situation, but it must be on one of the drives I'm not using
at the moment.

<i am fine with the transverse waves described by maxwell's equations
that don't require any aether.

Maxwell equations are for Heaviside aether:
http://www-groups.dcs.st-and.ac.uk/~history/Biographies/Heaviside.html
"I saw that it was great, greater, and greatest, with prodigious
possibilities in its power. I was determined to master the book... It took
me several years before I could understand as much as I possible could. Then
I set Maxwell aside and followed my own course. And I progressed much more
quickly.
Despite this hatred of rigour, Heaviside was able to greatly simplify
Maxwell's 20 equations in 20 variables, replacing them by four equations in
two variables. Today we call these 'Maxwell's equations' forgetting that
they are in fact 'Heaviside's equations'."

Heaviside equations have nothing common with Faraday and Maxwell.

I prefer the Faraday idea -  without any aether.
S*

it all depends on who is writing history:

"The four partial differential equations, now known as Maxwell's
equations, first appeared in fully developed form in Electricity and
Magnetism (1873). Most of this work was done by Maxwell at Glenlair
during the period between holding his London post and his taking up
the Cavendish chair. They are one of the great achievements of 19th-
century mathematics."

Yes, indeed it does matter who is "writing history." The quotation above is, in fact, quite wrong.

> "Maxwell's formulation of electromagnetism consisted of 20 equations in 20 variables. Heaviside employed the curl and divergence operators of the vector calculus to reformulate these 20 equations into four equations in four variables (B, E, J, and rho), the form by which they have been known ever since (see Maxwell's equations)."

This "writing of history" above comes from:
http://en.wikipedia.org/wiki/Heaviside
where the embedded link to (see Maxwell's equations) is:
http://en.wikipedia.org/wiki/Maxwell%27s_equations
which then "RE-WRITES HISTORY" to state that the forms of the four equations (formulated by Heaviside) were original to Maxwell (whose work of 20 are ignored).

This, of course, will have no effect on the Soviet-inspired revisionist polemic that un-informs this side thread from S* our amateur doctrinaire.

* * * * * *

As an experiment at translate.google.com, I entered that last paragraph above, translated it into Polish, and then took the Polish output and ran it through (in reverse as it were) to see what that looked like in English:

"This, of course, will not affect the relationship inspired revisionist polemic that does not inform the thread-by-S * our doctrinaire enthusiasts."

Curious how the "Soviet" was airbrushed out of translation.

So through carefully crafting the statement to preserve its piquancy, I amended it to:

This, of course, will have no effect on the Stalinist-inspired revisionist polemic that un-informs this side thread from S* our amateur doctrinaire.

English-Polish-English renders:

"This, of course, will have no impact on the Stalinist-inspired revisionist polemic that does not inform the thread-by-S * our doctrinaire enthusiasts."

Aside from the last plural in place of singular, quite faithful to the intended irony.

* * * * * * *

I wasn't going to try to push Maxwell's 20 equations through translate.google.com to see if Heaviside emerged.

In my first EE class, 'way back in the fall of 1962, the instructor
walked in and said "We shall study LLFPB", by which he meant

  Lumped, Linear, Finite, Passive, and BILATERAL

so I'd have to conclude that your bipole is one or more of
  not lumped and/or
  not linear and/or
  not finite and/or
  not passive.

<Yesterday, while repairing my antenna, something came to my mind I had never
<focused on before.

<Let us consider a bipole, that is a "black box" having TWO terminals and
<including plain passive elements only (like capacitors, inductors, ... , no
<diodes or other special devices), arranged the way you prefer, it does not
<matter.

<Instead of directly telling which it is, just for fun I wonder whether anyone
<can figure out a case in which a bipole may not be reversed without
<consequences. Not difficult, but it anyway requires some thinking.

You wrote: "Yes, indeed it does matter who is "writing history." The
quotation
above is, in fact, quite wrong."

So the best approach is to take a glance into the original papers.
In Maxwell's model the magnetic lines are like the smoke rings. Nothing flow
along them.
In Heaviside's model there is the solenoidal flow.

It is not simplification. The both models are quite different.

But the both are a history.

Your radio waves travel in rare plasma. It is interesting that Faraday
predicted it.

they may travel through a rare plasma, but the rare plasma is not
needed for their propagation.  they also travel through dense matter
like glass, but the glass is not needed for their propagation.

How about using a bicycle carrier and attaching the antenna to it? The
load would be better distributed.

"The velocity of light through space is about 190,000 miles in a second; the velocity of electricity is, by the experiments of Wheatstone, shown to be as great as this,"

For this reason Faraday concluded: " "I suppose we may compare together the matter of the aether
and ordinary matter (as, for instance, the copper of the wire through which the electricity is conducted), and consider them as alike in their essential constitution; i.e. either as both composed of little nuclei, considered in the abstract as matter"

Everywhere are "nuclei" (electrons).

You simply do not read Faraday.

He also described a dipole: " For suppose two bodies, A B, distant from each other and under mutual action, and therefore connected by lines of force, and let us fix our attention upon one resultant of force, having an invariable direction as regards space; if one of the bodies move in the least degree right or left, or if its power be shifted for a moment within the mass (neither of these cases being difficult to realise if A and B be either electric or magnetic bodies), then an effect equivalent to a lateral disturbance will take place in the resultant upon which we are fixing our attention; for, either it will increase in force whilst the neighboring results are diminishing, or it will fall in force as they are increasing."

" if its power be shifted for a moment within the mass" = if electrons oscillate in a dipole.

Wimpie mentioned a monopole. Dipole = two monopole.

What does monopole radiate?

In your antennas and in the space are free electrons. We do not need a mystery TEM..
S*

Depends. If the monopole is pointed upwards, it radiates positive half
cycles of RF. If pointed downwards, negative half cycles are radiated.

what about if it is horizontal???   or as art prefers, tipped at some
angle??

Faraday was proven wrong many times by much later experiments... the same for all other aether models. EM waves do not need aether or your free electrons.

It would be interesting to see one such example.

Faraday's classic "The Chemical History of a Candle" may be expressed in archaic language (not really that archaic once you get into the vernacular), but it is an example of extremely clear analysis and instruction. There is absolutely nothing wrong anywhere in that recital.

Faraday examined the properties of induction - action at a distance - in equally archaic terms, but with scientifically rigorous methods. The archaic language was confined to terms of invention. Phlogiston, as both a term and concept, was an invented word that was current during his life.

I am sure he used the Phlogiston in correspondence with those who understood its context. However, the nature of that correspondence reveals that neither party "believed" in it as a force of nature, and merely used the term and concept as a touchstone insofar as it was a focus of debate.

In other words, for them the debate was over and Phlogiston was an intellectual dead-end, but the focus of the underlying question it was supposed to have answered was a question still being discussed.

Depends on which way it's pointing. If North, positive half cycles go West and negative half cycles go East.

If it is tipped to an undefined angle, the positive and negative half cycles get confused and the electrons refuse to jump off. This makes it good only for receiving.

that's actually a pretty good idea...may interfere with the
hatchback...someone here had the idea of a luggage rack, but grounding
may be an  issue..

no good solutions!

ah, that would be good for art since nobody wants to hear what he has
to say anyway.

There really are no good solutions for these newer toy
cars. That's why I don't have an antenna on my Corolla
even 3-4 years after I bought it. :/ Not even a 2m whip.
I had an Accord before the Corolla, and I drilled a
hole in the trunk and reinforced it with plates under
the trunk. It still distorted the thin metal of the trunk
after a while. My antennas are tall, and I *will* hit
something sooner or later. Usually trees.. But even the
lower stress of highway speed wind will distort one after
a while. The bike racks can be used, but you would have to
search long and hard to find a worse place to mount an
antenna. The ground losses will be much greater than any
antenna mounted up on the car. I don't care how well it's
grounded via wires.. The wire grounding scheme with little
metal under the base of the antenna just doesn't get it done.
It will be a good DC ground, but a piss poor RF ground.
Expect performance to basically suck.. :(
So... I've pretty much given up trying to mount an antenna
on that car. It will end up trashing my car, and being as it's
still fairly pristine, I'm not willing to do it.
I've still got my old trucks if I really have to have a radio
and antenna. They have antenna mounts which work well and
never a concern about warping metal. I just have to cough up
lots more for gas.
When I drive up to my place in OK, it's a 900 mile round trip,
and I drive the car to save gas. I just go without a radio until
I get there. I have dipoles in the trees there, with 100 ft of

```
coax that I keep rolled up on a tree branch stump. I miss the
radio on the drive, but not enough to butcher up my car.  :/

I see that you understand the Faraday's " archaic language ".
You know also that Faraday newer was wrong.
And, "Yes, indeed it does matter who is "writing history."

In a history by S. Errede is wrote: "Faraday inspired by his discovery of
the magnetic rotation of thinks that it might be transverse vibrations of
his beloved field lines"

Is Errede right?

Faraday wrote: " It seems to me, that the resultant of two or more lines of force is in an apt condition for that action which may be considered as equivalent to a lateral vibration; whereas a uniform medium, like the aether, does not appear apt, or more apt than air or water."

For me he wrote: "The resultant of two or more monopoles is equivalent to a lateral vibrations".

Like the "if its power be shifted for a moment within the mass (neither of these cases being difficult to realise if A and B be either electric or magnetic bodies), then an effect equivalent to a lateral disturbance will take place in the resultant upon which we are fixing our attention.."

What your dipole prodce: TEM waves or "an effect equivalent to a lateral disturbance " ?
S*

you must remember, that just because any of those old guys wrote
something it doesn't mean that they believed it even a year later.
they were all putting up theories and trying to connect electricity
and magnetism with just about anything else for many years.  it was
even many years before anyone figured out that electricity and
magnetism were related.  you would learn much more by using a modern
text that has filtered out all the theories that were thrown away than
reading the raw conjectures of early theorists.

I can find tubing with a .120" wall, and I can find it with .058" wall.

For a short run (just a few feet), would there be any significant difference in bending resistance between a length of the thick wall stuff and one made from two nested thin wall lengths?

Weight's not an issue, nor is price.

Interesting design, as it is shorter than a standard ground plane
vertical. Have you built and tested one?

   So what is wrong with winding a "second" layer with only a few truns
(say 1/20 of larger coil) and connecting it series aiding, use whole
"tapped" (now) coil for the LC resonance and the use that (new) tap?
   Besides, if it is not would, the amount of the wire would be no
```

different wether you put a tap in or not.

Hi Jake,

The problem is with a radio station you are NOT listening to that
overwhelms you receiver and silences the other (or forces a new
station over the) station you ARE listening to. This comes from the
lack of a tuned circuit in the receiver.

Your manual tune radio apparently has just such a tuned circuit which you adjust by hand with the twist of a knob (old-school). Cheap sets are tuned digitally (even though some of them, too, have a twist knob to do it) and have no tuned circuit. What you describe is the classic difference between the two, and living in a dense urban environment increases the number AND proximity of strong stations that could lead to this problem you describe.

If you have the provision for attaching an external antenna to the problem receivers, then using a "rabbit ears" antenna, with careful length adjustment might help (but it would seem unlikely). Notch filters would also offer help, but this may be too sophisticated for you if you are not a Ham or techie, and you are just visiting our forum to tap our experience (which is perfectly OK).

>
>Does this seem like a situation where the one is likely to overwhelm the
>other, especially considering that they're not exactly neighbors on the
>dial? As a general matter, is it normal for a tuner to pick up separate
>frequencies when tuned to one?

It is found in all single conversion receivers and is called "Image" reception. It can be observed when the interfering station is different from the one you are listening to by twice the Intermediate Frequency. For FM, the IF (Intermediate Frequency) is generally 10.5 MHz. Now, given the FM band is only 20MHz wide, this condition is not commonly found in FM receivers. However, there are other transmitters nearby in the TV low VHF bands (if they have not gone dormant due to the DTV conversion). The aviation band is above FM, but it would seem unlikely to be the source of your problem by this mechanism.

Then it could be a very strong signal crowding its way in.

Saving a few cents on Lits wire will cost you almost half of the power
you could deliver to the tank.

This won't give you maximum power transfer.

Correction: You'll lose much more than half the power.

 Nothing wrong with that at all, there are many ways to build a crystal
radio.
Here's just 77 of them.
              Have fun, Mikek

Hi Joe,

Care to go deeper?  Would that "more than half the power" be 3.1dB?
6dB?  20dB?

Why "half the power" as a round number instead of a tenth?

73's

would prefer not cutting the car. on my old honda CRV i had a piece of
angled aluminim i bolted to the spare tire mount. the element is
protrusion free, unfortunately, so there's nothing to hang anything on

Why, because I chose not to go into detail.

If you look only at a resistive source impedance, the most power we can get is

((Vsource/2)**2)/Rsource

Now the example starts with Rsource = 58 ohms and is trying to transform that to match a 1.5 Meg load. The power available from a source with 1.5 M source impedance is much less than that from a 58 ohm source.

Hint : 58/1.5M

So, doing something to match the tank to the load could be much more effective. A tapped coil or additional winding has been suggested.

Hi Joe,

It is a given that from the power available in the field, only half of it at most will be captured - ever.

>So, doing something to match the tank to the load could be much more
>effective. A tapped coil or additional winding has been suggested.

Well, the discussion took a branch into resistive networks for the simplicity of discussion, not as an example of a solution to the practical problem.

A tapped coil is an excellant choice, of course, I offered that option myself. A secondary coil, also suggested, is just as useful.

hi howard and thanks...no, i checked that. the element is barren of
any attachment points...very well thought out!

i used to have a screwdriver. liked it but it was a BITCH to ground
and it wouldnt work right without a great ground...

but looking at the mounts for the high sierra may give me some
ideas....

thanks, joe! that's a possibility and it would get the whip above roof
level.

Some years back, I went to a welding shop and asked them to weld a steel
strap to the car for an antenna mount.  They found a spot on the left rear
where the strap would stick out and hold a mobile antenna.  The shop rounded
the edges on the part of the strap sticking out, and drilled a hole in the
strap for the insulated whip connector.  It worked out great.

I drilled a hole in the ceneter of the roof of my wifes Nissan. Two
years later traded it in. I removed the antenna mount and plugged it
with a snap in rubber plug. No effect on resale value.

Jimmie

I'm about to install a 125 ft long antenna 30 ft high.
Is there any advantage to bringing the far end back
down to the ground or near the ground.
What does this extra wire do to the impedance?
Pattern?

Thanks, Mikek

It will probably lower the various 'natural' resonant frequencies a
little, and also change the angles and directions of signal pickup.
However, I don't think that you're unlikely to notice much difference.

If you do want to bring the far end down to ground level, you might like
to consider the potential reduction of local noise by inserting a
(typically) 9:1 impedance transformer and far end ground, and bringing
the RF signal back to the house via coax.

I got the wire up this morning/afternoon, I did leave the wire long at the
far end so
it will reach the ground. I'm not sure what I will do with it yet.
 I'll add a little more info, it will have a dual purpose, First, I'm going
to characterize
it as a long wire for use with a crystal radio. I want to optimize it for
that.
 I had thought about running a counterpoise along a fence, but I found a
better
tree that runs at an angle to the fence. How close does a counterpoise need
to
follow the antenna?

How do you think a chain link fence will work as a (grounded) counterpoise?

 When the crystal radio excitement has run its course, I'll use it as an
antenna for
my general coverage radio, with that it's still mostly am BCB, but some 80
meter
listening too.
                      Thanks, Mikek

  I recall an article in QST or "73", I think the title was,
  "For the L of it"
  I'm looking for the magazine it was in and the date it was printed.
 The article described  a series LC, a fixed L and a air variable C.
The impedance of  the L was bigger than the impedance of the C,
and by adjusting the C you caused the inductance to vary.
So in effect you have a variable inductor.
            Thanks,    Mikek

Carry a piggy bank in the car.  Every time you hit something, throw a fiver
in the bank.  Pretty soon, you will remember.

Or two caps in series connected paralell to an inductor. Input or
output at the juction of the caps. This concept of the circuit may be
more easily found in various reference manuals. You may find these
caps labeled TUNE and LOAD in some circuits.

> =A0 =A0 =A0 =A0 =A0 =A0 Thanks, =A0 =A0Mikek

I recall the article and have it around somewhere. The problem with
this (if you want to call it a problem) is it only works for a small
range of frequencies.

For instance, at 10 MHZ a series 1.6uH L and 318 pF C looks like a .
8uH inductor (good). But at 5.76 MHZ the combination looks like 30
ohm Xc capacitor. At 7.0 MHZ it looks like a short because of series
resonance.

I would not want to replace the roller inductor on my 80-10 antenna
tuner with this, but there are other applications (single frequency)
where it should work just fine.

Gary N4AST

Andy adds:

    Another way to accomplish the coil isolation would be to use a
1:1
50 ohm wideband transformer from Mini-Ckts lab. They are only a
couple dollars...
   If you have a good parts box, you can wind one yourself as they are
very simple. The ARRL handbook can give you guidance if you are
not  familiar with the technique. Simply a bifilar winding around a
small ferrite toroid.....

   I'd also still use a couple of backtoback diodes, in parallel with
a
neon lamp.  Couldn't hurt........ might help, once.......

Back to back diodes will cause a problem if you have strong signals in
the area (enough to get the diodes to start to conduct) from intermod.

Neon lamp fires at 60-70 volts.. hopefully whatever is downstream can
tolerate that.

It's a classic problem.. all the things that protect the front end also
degrade the performance in one way or another.  You have to make the
decision about whether you want best performance and highest risk or
vice versa.

PstRotator is a program for antenna rotators control -
http://www.qsl.net/yo3dmu/index_Page346.htm
It works with a wide variety of rotators, supports a lot of loggers,
DX cluster clients, satellites and moon trackers, and supports multi-user remote operation over the Internet. The user interface offers
quite a selection of methods for pointing and display, as well.

PstRotator is a program for antenna rotators control -
http://www.qsl.net/yo3dmu/index_Page346.htm
It works with a wide variety of rotators, supports a lot of loggers,
DX cluster clients, satellites and moon trackers, and supports multi-user remote operation over the Internet. The user interface offers
quite a selection of methods for pointing and display, as well.

I put up a long wire antenna, it is an inverted C.
The antenna is resonant at 3.55 Mhz.
I want to characterize it an the AM broadcast band.
 I have made a measurement at 500 Khz and I had to install a parallel capacitor
to get my variable inductor to bring phase to zero.
 I don't know how to do the math to find the impedance of the antenna
with the L and C in the circuit.
 Can someone look at my drawing and give me the math so I can figure out
the impedance. Then I can get the numbers at other frequencies for the band

and calculate those impedances.
See drawing here. I want to calculate the Unknown Impedance.
I need the R and the C of the antenna.
http://i395.photobucket.com/albums/pp37/Qmavam/Antennaat500Khz.jpg

I cheated. I used a Smith chart.

It is 170 - j530.

Cheers,
John

Work backwards. You have a 55 ohm resistor in series with a 310 ohm reactance. Get the equivalent parallel combination of that (the complex reciprocal). Take the reciprocal of the capacitor (just invert the Xc and change the sign). Add the two complex numbers. Take the reciprocal of the answer. This is the impedance the antenna sees looking into the network. The antenna is the complex conjugate of that (just swap the sign of the imaginary part).

Does this help?

John

Dear Mikek (no call sign):

Assuming that the inductor is 3 +j310 because it must have some loss and calling the capacitor -j717, my trusty calculator estimates the antenna looks like 159 -j526. The real part seems high - probably due to ground losses.

However, the idea that even such a simple an antenna can be modeled as an R and C over the AM broadcast frequency range seems unlikely.

An instrument such as the AIM4170C would provide Z with greater confidence and do so at each frequency of interest. However, in the broadcast band it is not clear that such a set of impedances can be used for something useful. What is the actual goal?

Regards,   Mac

I don't know, I not there yet.

55 + i310
complex reciprocal
55 - i310 / 55^2 + 310^2
reduce
55 - i310 / 3025 + 96100
reduce further
55 - i310 / 99125
Take the reciprocal of the capacitor (just invert the Xc and change the sign).
Xc = -i717 so 1/i717 ???
Add the two complex numbers.
(55 - i310 / 99125) + (1/i717)
Any mistakes yet?
Going further doesn't get me the answer you have.
Mikek

From what I have read it seems very high, could I have 130 ohms of ground loss?
I don't think so.

I'll be looking into the ground, I think it is just a 6 foot rod, I put it in years ago.
I'll add FWIW, I connected the AC ground from a receptacle and it made zero change.

> However, the idea that even such a simple an antenna can be modeled as an

Ya, that's not the plan, I'll check it every 100 khz and make a graph, with R and C.

> An instrument such as the AIM4170C would provide Z with greater confidence

> useful. What is the actual goal?

I put the antenna up for multiple use, but to start, I want to use it with a crystal radio,
the measurements may help me figure out the series cap (range) needed to make an
R match to the tank circuit over the band.
And it's a project that forces me learn some math.
Thanks, Mikek

Well, no, but you should simplify here.

> Going further doesn't get me the answer you have.

I can't tell why because you didn't show your work.

>   Mikek
>
>

Convert the series impedance 55 + j310 to its parallel equivalent admittance (1/(55+j310) as follows:

1/(55+j310) = (55-j310)/(55+j310)(55-j310)

In other words, multiply the numerator AND denominator of 1/(55+j310) by the conjugate (55-j310) of the denominator.

This gives (55-j310)/(3025+96100) or (55-j310)/99125 which is an admittance of 554.85e-6-j3.127e-3.

The capacitor's parallel equivalent admittance is 1/(0-j717). So, when numerator and denominator are multiplied by the conjugate we get

0+j717)/(0+514.089e3) or j717/514.089e3 which is 0+1.395e-3.

Now the sum of (554.85e-6 - j3.127) and (0 + 1.945e-6) is

554.855e-6 - j1.733e-3

This the parallel equivalent (the admittance) of your components and what the antenna is seeing.

Following in the steps of my second and third sentences above, the equivalent series impedance of your network looking back toward the resistor is the reciprocal of that, or

167.63 + j523.5

This is the impedance the antenna sees. The antenna's equivalent impedance is the conjugate of that. That is, the antenna looks like an impedance of 167.63 - j523.5 according to your data.

A calculator that handles complex numbers is invaluable. I have one on my computer's desktop. I also have an electronic Smith chart which is usually faster. If you need a link, let me know.

This whole thing may look a bit complicated to you if you are not
familiar with complex numbers. Look up how to do X, /, +, - using
complex numbers and get familiar. It will help.

Cheers,
John

One other possibility is one of the four magnet magmount setups. Some even
come with coax. I've even seen such mounts used for screwdrivers if you
still have your prior one. Before anyone points out they have to be
grounded properly, the mounting holes for the roof mount offer access to at

least some grounding with the proper short bolt. I suspect such a scheme might have the grounding strap()/wire(s) too long at 10 meters, but for 17 meters through 75, probably should be adequate.

anks, Mikek
```

Seems like it doesn't much matter whether the antenna is real or imagined; the point is rather what's going on when you couple a low impedance source to a parallel-resonant tank through a small capacitance...

Perhaps it will help you to think first about a low impedance source, let's say 50 ohms at 1.591MHz (1e7 radians/sec), that you want to couple to an (imaginary) inductor, 2.5mH with Qu=3D500 at that frequency, and maximize the energy transfer to the inductor. The inductance and Q implies that the effective series resistance of the inductor is 50 ohms. That means all we need to do is cancel out the inductive reactance, and we can do that with a series capacitance--that happens to be 4pF. That assumes the ESR of the capacitance is zero, or essentially zero.

But what if the inductor has 1/4 as much inductance, 0.625mH, same Qu? Then its effective series resistance is 1/4 as much, or 12.5 ohms, and to get the same energy dissipated in it, you need the current through it to be 2 times as large as before (constant R*I^2). The total capacitance to resonate the tank is 4 times as much: 16pF. If you divide that into two 8pF caps, one directly across the inductor and the other in series with the 50 ohm source, (very close to) half the tank's circulating current flows in each capacitor. For the same energy delivered to the coil, the voltage at the top of the inductor must be half as much as before. Since the coupling capacitor to the source is twice as large as it was before, the load impedance the source sees must be the same as before (50 ohms, as required for max energy transfer).

Carry that another step, to an inductor with 1/16 the original inductance and the same Qu=3D500, and you need 64pF to resonate it and 16pF to couple to it from the low impedance source. Now you divide up the total capacitance with 3/4 of it (48pF) directly across the inductor and 1/4 of it to the source. 3/4 of the tank's circulating current flows in the 48pF capacitor, and 1/4 of it in the 16pF to the source; the source once again sees a 50 ohm load (because the voltage

at the top of the inductor is 1/4 of the original, and the capacitor
coupling to the source is 4 times as large -- with the current in the
source unchanged).

The key to understanding this coupling, to me, is the division of the
tank's circulating current between the two capacitances, one directly
across the coil and one in series with the source. The smaller the
inductance (at constant Q), the more circulating current required for
the same energy dissipation, and the smaller
_percentage_of_total_resonating_capacitance_ for coupling to the
(constant impedance) source.

Cheers,
Tom

```

At resonance, the LC tank disappears and you are left with a 1.5 Meg equivalent of the tank losses.

Adding a small capacitance in series with your antenna gives you, effectively, an antenna that looks like a 58R in series with a 17 pF capacitor.

So now your circuit looks like:

```
58R---17pF-----|
                |
               1.5M
                |
                |
               ----
               GND
```

I don't see any conversion at all.

John

Ah! After studying this for a while, I think I understand what you are driving at.

Convert series 58R and 17 pF to a parallel equivalent. That is, take the reciprocal of Z = 58 - 9368j to get Y = 661e-9 + 106.8e-6.

Now, what is the reciprocal of the real part of Y? That's 1/661e-9 or about 1.5 Meg. So, the real part of the parallel equivalent now looks like the resistance you are interested in.

Does this help?

Cheers,
John

Hi Greg,

No, that would more likely result in a characteristic Z of 600 Ohms.
If by being close to ground you mean the 58 Ohms finds itself invested
in the dirt, well, yes that might be the case.

The long and short of it means that to investigate the problems of an
antenna "loading" a tank coil means that you really must understand
the antenna - not a simple thing as this thread will undoubtedly
reveal.

Hi Mike,

Then your intuition is firing on all cylinders, great.

>Here's what is stated in the article:
> " The concept is that at any given frequency, a parallel RC network has an
>equivalent
>series RC network, and vise versa.

This is classically true. The frill of "at any given frequency" can
be discarded.

>We can use this property to transform the
>real component
>of an impedance to a much higher or lower value.

This concept is not a "property," however; more a transformation (as
should be apparent in the original statement). In other words
concept
equivalent
property
transform
use four words to describe one thing - transform (plain and simple).

>As long as Xc series >> R series.
>Xc (parallel) = Xc (series)
>R (parallel) = XC^2 (series) / R (series)
> The Xc of a 17pf at 1Mhz is 9368 Ohms.
>To rewrite Rp= 9368^2 / R = 1.513 Mohms

Well, what looks like hand-waving is probably close to the numbers one
could expect.

>The article then goes on to say,
>The utility of this equivalence can be seen by choosing a sufficiently small
>value of C series
>(a large Xc series) A "small" resistance can then be transformed into a
>"large" value.

The reason why I say hand-waving (and this is probably your gut
reaction as to "why") is that the five lines of operations you quote
starts with a presumed requirement and then proves it has been met.

What happens if Xc series << R series?
What happens if Xc series < R series?
What happens if Xc series = R series?
What happens if Xc series > R series?

This somewhat clouds the mystery for you of understanding Parallel to Series conversion. I wonder too. Are we dropping in a new component and stepping back with a wave and Voila! to find the Parallel circuit has suddenly been transformed? Yeah, that WOULD be a mystery.

And what is this Xc(parallel) and Xc(series) stuff?

Xc is stricty a function of pi, capacitance, and frequency.

And what is this R(parallel) and R(series) stuff?

R is a function of its, well, resistance. No variables to be found.

No doubt there is more to be extracted from this article.

Upon review of other correspondents to your plight, ditch the article
and pick up an EE sophomore book on circuit analysis. The coverage
should be encompassed in the section (from my own copy) called
"Transform Driving Point Impedance and Admittance (Immittance)."

The article's focus is on matching a crystal radio tank to the antenna,
So as a general statement, the tank is a high impedance (mostly R)
and the antenna has a low R and a C in the 100's of ohms.
So I don't know, is that (>>) ?   The question is retorical in nature.

> And what is this Xc(parallel) and Xc(series) stuff?

I took a little liberty there, The article had a schematic diagram showing
a series RC, then the radio showing the Parallel equivalent antenna
connected.
The the actual labels were Xs, Xp, Rs, and Rp.
Sorry if I muddied it, the attempt was to make it clearer.

Seems like it doesn't much matter whether the antenna is real or imagined; the point is rather what's going on when you couple a low impedance source to a parallel-resonant tank through a small capacitance...

Perhaps it will help you to think first about a low impedance source, let's say 50 ohms at 1.591MHz (1e7 radians/sec), that you want to couple to an (imaginary) inductor, 2.5mH with Qu=500 at that frequency, and maximize the energy transfer to the inductor. The inductance and Q implies that the effective series resistance of the inductor is 50 ohms. That means all we need to do is cancel out the inductive reactance, and we can do that with a series capacitance--that happens to be 4pF. That assumes the ESR of the capacitance is zero, or essentially zero.

But what if the inductor has 1/4 as much inductance, 0.625mH, same Qu? Then its effective series resistance is 1/4 as much, or 12.5 ohms, and to get the same energy dissipated in it, you need the current through it to be 2 times as large as before (constant R*I^2). The total capacitance to resonate the tank is 4 times as much: 16pF. If you divide that into two 8pF caps, one directly across the inductor and the other in series with the 50 ohm source, (very close to) half the tank's circulating current flows in each capacitor. For the same energy delivered to the coil, the voltage at the top of the inductor must be half as much as before. Since the coupling capacitor to the source is twice as large as it was before, the load impedance the source sees must be the same as before (50 ohms, as required for max energy transfer).

Carry that another step, to an inductor with 1/16 the original inductance and the same Qu=500, and you need 64pF to resonate it and 16pF to couple to it from the low impedance source. Now you divide up the total capacitance with 3/4 of it (48pF) directly across the inductor and 1/4 of it to the source. 3/4 of the tank's circulating current flows in the 48pF capacitor, and 1/4 of it in the 16pF to the source; the source once again sees a 50 ohm load (because the voltage at the top of the inductor is 1/4 of the original, and the capacitor coupling to the source is 4 times as large -- with the current in the source unchanged).

The key to understanding this coupling, to me, is the division of the tank's circulating current between the two capacitances, one directly across the coil and one in series with the source. The smaller the

inductance (at constant Q), the more circulating current required for
the same energy dissipation, and the smaller
_percentage_of_total_resonating_capacitance_ for coupling to the
(constant impedance) source.

Cheers,
Tom

Tom I need to print this out and work with it.
Did you change the inductor on purpose or just miss a
factor of ten from the numbers I posted?
Thanks, Mikek

Hi Jake,

Sounds like the two Sonys are being overwhelmed by a strong local station. They have no front-end tuning to make them as selective as your, as you describe, analog tuned clock radio.

Mikek,

on of the main problem of this newsgroup is that people write answers without carefully reading the question.

Everyone tends to "convert" the question toward issues he is able to write something about, Unfortunately those issues often have little to do with the original question.

I am offering you my answer, which may be clear, so and.so, or hardly understandable ... I do not know. But be sure that at least I paid maximum efforts to appreciate your question (though my numbers do not always match yours). I'll try to explain the issue in the easiest way I can, assumimng that all components behave in an ideal manner.

Let us first resume your hypotheses:

- the antenna has an impedance equal to the SERIES of a 58-ohm resistance and a capacitive reactance of -1,072 ohms which, at 1 MHz, corresponds to a 148.5-pF capacitance
- your aim is to transform that complex impedance into a 1.5-Mohm purely-resistive impedance, that would match that of your tank circuit.

That said, you must first appreciate that your antenna can be visualized in two ways:

- as the SERIES of R=58ohm, C=148.5pF (as said above)
- or, by applying the series-to-parallel transformation formula, as the PARALLEL of R=19,862ohm, C=148.1pF

These are just two fully equivalent ways of describing the same physical antenna. You can freely use the one which suits you best. For our purposes let us here visualize your antenna as the parallel of R=19,862ohm, C=148.1pF.

That said, assume for a moment that you are able to eliminate in some way (i'll tell you after how) the 148.1-pF parallel capacitance. What would then remain is a 19,862-ohm resistance, a value which unfortunately does not match the 1.5-Mohm figure you wish to get.

So, how to get just 1.5Mohm instead?

Playing with the transformation formulas you would realize that, if the SERIES representation of your antenna would hypothetically be R=58 ohm, C=54 pF (instead of R=58 ohm, C=148.5 pF as it is in the reality), the corresponding PARALLEL representation would then become R=1.5Mohm, C=53.9 pF. Just the resistance value you wish to get!

But modifying the SERIES representation of your antenna according to your needs is very easy: if you put an 85-pF capacitance in series with the antenna, its total capacitance would change from C=148.1 pF to C=54pf. And the antenna SERIES representation would then become R=58 ohm, C=54 pF, as you were aiming at.

Once you have put such 85-pF capacitance in series with your antenna, its PARALLEL representation becomes R=1.5 MHohm, C=53.9 pF, as said earlier.

For removing the 53.9-pF residual parallel capacitance, just resonate it with a 470-uH parallel inductance. The trick is then done: what remains is just the 1.5-Mohm resistance you wanted to get!

In summary:
- put a 85-pF in series (i.e. in between your antenna and the tank circuit)
- put a 470uH inductance in parallel to the tank (in practice this just means to increase the tank inductance by 470uH with respect to its nominal value).

Hi Mike,

There's your first mistake. Tank Z is never, ever "mostly R," or you wouldn't be able to make the Q claim of 1000 (or even 10).

Please note the distinction between Z (which includes R) and R in isolation. Further, read Terman's material on Tank Circuits in his classic "Electronic and Radio Engineering" to clear up the clouds that obscure the view of their design rationale.

>and the antenna has a low R and a C in the 100's of ohms.

This is the sad (and useful) fate of short antennas, yes.

> So I don't know, is that (>>) ?   The question is retorical in nature.

It is usually rhetorical, yes, insofar as not being enumerated. Often in technology it is a shorthand for a 10:1 ratio. Perhaps 100:1.

>> And what is this Xc(parallel) and Xc(series) stuff?
>
> I took a little liberty there, The article had a schematic diagram showing

I could follow Xc(parallel/series) easily enough, but what you neglected to mention was there are two schematics embodied in the single one you brought to the discussion.

Making questions simpler often leads to Byzantine answers.

Another problem in this simplification is that there is more than one agenda being served, and they sometimes conflict with any single solution. As often happens, when I ask "What do you really want?" I get a response, I offer a solution, and I am immediately rebuffed that it does not serve the other agenda - which, then leads me to ask "What do you really want?"

Antonio - I think you slipped a decimal point. The parallel equivalent
of the series combo 58R-2947j is actually 149k+2948j.

Hi Tony,

Great walk-through, excellent solution. And the appearance of Two
additional, unstated components. Are they found in the original text
of the article? Possibly not and thus the source of mystery (and a
cautionary tale about what might be found as knowledge on the
Internet).

Mike, I don't care what your values are. I'm interested in showing
you in the generalized _concept_: how it works. Once you understand
that, you can work with whatever component values you want. If you
want to actually build something that works, you better pick values
you can realize.

Cheers,
Tom

Never heard of that before, and I know lots of people who've used them
over the 30+ year period they've been around.  Including myself.  I'd
like to see pictures.  And also know how much power the guy was sending
```

to an antenna system rated for a specific number of watts.

Ok, Richard that wasn't clear to me, I think at resonance the tank is
all R, but I put mostly R because I figured you would have an objection to
all R. So are you saying it is pure R at resonance?

>......which, then leads me to ask

>"What do you really want?"
>
> 73's
> Richard Clark, KB7QHC

I want to understand the use of an air variable to match an antenna
to the tank of a crystal radio, over the AMBCB frequency range.
With that, I found I need to understand the series to parallel conversion,
which I now understand, just IS, it's not anything you do. A series RC has
a parallel RC equivalent.
I'm not sure how it can be both at the same time. But as long as that R is
transformed up, and minimally loads my tank, that's all good.
Then, I understand I still have C left that I can use as part of the C for
resonating my LC tank.
Mikek

Sorry, how much power the system was _rated_ for. You stated 50 watts
delivered. Also whether he installed it correctly and tuned it correctly.

You've got it now, Mike. The series/parallel equivalent circuits are
just a mathematical tool for putting things in a form you can handle
easier. Adding the capacitor does not change the circuit from series to
parallel or the other way around.

Lets say you have a fixed frequency AC source, a resistor, and a
capacitor. The R and C is in a box where you can't see how they are
wired. You measure the voltage applied to the box and measure the
current (with phase) into the box.

You could calculate the value of the R and C, right? Most people would
calculate them as an R in series with a C. But, there is a parallel R
```

(of a different value from the series case) and a parallel C (of a different value) which will give the same measurements as the series case. You cannot tell which way they are wired internally and, because of this, you cannot tell the actual values of the components. But, for analysis or synthesis, it won't matter.

You can mathematically change a circuit around from series (impedance) to parallel (admittance). This is the conversion that you've been hung up on.

Does this make any sense?

Cheers,
John

Ya, I have a better understanding now. I need to run a few cases and
see the minimum and maximum capacitor needed for a proposed situation.
I wish it would warm up, I'd like to put up an antenna and measure it, to
get a real case to work with.
Mikek

What I found to be most instructive, in understanding this (that is, series representations vs. parallel representations) was to drop down a level into the underlying mathematics.

Start with the fact that you have two impedances (let's call them Z1 and Z2) which are in parallel.

Toss in the basic formula for the result:

Ztot = (Z1 * Z2) / (Z1 + Z2)

Since you have a resistor R and a capacitor C in parallel, Z1 is a real number (it's just R), and Z2 will be an imaginary number (it's -i/2piFC, or 1/jWC if you prefer engineering notations and squint at the "W" so it looks like an omega).

Plug these values into the equation above, and simplify according to the rules for complex number mathematics. You'll end up with Ztot being a complex number, equal to the sum of a pure resistance (real) and a pure capacitance (imaginary). These are the impedances of the series network equivalent to your original parallel network.

Alternate route to the same solution: take each of the two impedances and invert them, to determine the admittances of the two components. The admittance of R will be purely real, while the admittance of C will be purely imaginary. Add the two together (since they're in parallel) to get the complex admittance of the parallel combination. Now, invert this complex number according to the usual rules, to get the equivalent complex impedance... this will be a complex number, the sum of a pure resistance and a pure capacitance. The numbers you get will be the same as in the previous work-through.

Mike -

Look into getting and learning (free) LTSpice for circuit analysis.

Also look into getting and learning EZNEC (free) for antenna analysis.

You can't beat putting up an antenna and building a circuit for it and
measuring results. But, during adverse weather, you can experiment with
simulation software and learn a lot. Then you can try your simulated
experiments when the wx is good.

Cheers,
John

Thank you for the excellent suggestions, Geoff! I live in the boonies - the
nearest repeater is about 15 miles away and no line of sight with it - at
least not at ground level. All of the others are considerably farther away

and no line of sight with them, either (lots of mountains here). I already have a short SMA adapter cable for my mobile antenna, and a speaker/mic too.

Amen!

I love to build antennas and I could not do it without some form of measurement device to determine the characteristics of the in-work project. I usually go by VSWR and alter the design in various ways (often slight changes to element lengths) to minimize the VSWR at my chosen freq. a VHF/UHF VSWR meter can be had for peanuts but a 250-dollar antenna analyzer will be in your future if you get a case of Antenna Fever. (Yeah, I have one.) However, as you are just getting started, try reading this: http://kb6nu.com/no-vhf-swr-meter-no-problem/

I like working in copper pipe at VHF and above. It's very durable and responds well to a Home Depot propane torch for so-called "sweat soldering." Copper pipe comes in several grades. The cheapest grade seems to make antennas that are just fine.

Welcome to the hobby.

Sorry, too, that this was years ago and I cannot recall the source.  I
looked for something (anything) before I posted, came up with nothing
and almost didn't post it.  More looking just now, trying different
search terms and still nothing.  Maybe it was BS.  One lone story
isn't very impressive.

>all R. So are you saying it is pure R at resonance?

Hi Mike,

Let's say there is absolutely no loss in the Tank (superconduction and perfect dissipation values as it were); then we would have to ask ourselves what happens to energy applied to this Tank at resonance? It can never enter it, thus the Tank is, in effect, infinite in resistance. But what about the circulating currents? The Tank is, in effect, infinite in conductance.

Infinite Ohms & Zero Ohms simultaneously.

Is this the Z of the Tank? Is this the R of the Tank to which you are matching? No, not even close and certainly it has nothing to do with resonance - except the condition is a function of it being at resonance. A low Z Tank or a high Z Tank each evidences the same Infinite Ohms & Zero Ohms simultaneity given my initial condition of absolute losslessness.

For the energy being applied to or drawn from the Tank, the Tank is in parallel operation. For energy in the Tank, the Tank is in series operation. Where is the Q in this duality? Q suffers by the nature of what you call R. Q has two different values by this duality. One is called "Loaded Q" and as you might guess, the second is called "Unloaded Q." Consult Terman for the engineering design rationale for optimal Qs as I suggested.

When the discussion of "matching" seeks to employ R (pure resistance), then the next step is toward a conjugate match and elaborations of efficiency and maximum transfer of power. There is also an alternative discussion called the Zo Match. This second match seems to invite the same elaborations (many who post here try to force them both into the same salad bowl and cover the illogic with dressing).

When you offered the comment about "the tank is a high impedance (mostly R)" it was steering the car off the cliff. Is this a Zo match or a Conjugate match you are seeking? (I can already anticipate this has gone over your head, as well as many readers. This and the questions that follow are rhetorical.)

For instance, and returning to antennas (the purpose of this group's discussion focus), you can have very high Z antennas with very low resistance characteristics. Do you want a Zo Match, or a Conjugate Match? Let me flip the antenna: you can have very high Z antennas with very high resistance characteristics. Do you want a Zo Match, or a Conjugate Match? Let's do this sideways: you can have very low Z antennas with very low resistance characteristics. Do you want a Zo Match, or a Conjugate Match? I could box the compass here, but the I think I will let the reader off.

>   Mikek

John had some number issues with Tony's explanation, but the gist of Tony's rational treatment should be your lesson as it provides for your requested "why." It also implies (by my comments of the sudden appearance of two new components) that our (Ham) tuners have been designed to introduce the proper amounts of reactances in the proper parallel/series relationships to enable the necessary transform towards optimal Q and loading balance. The most elaborate of tuners can change from Pi to T topologies, or series L parallel C (or series C parallel L), or series LC, or parallel LC, or parallel C series L (or parallel L series C)... and any of the other combinations I have not enumerated (about 9 in all). Each shines for a particular situation - you have named only one.

It is not a trivial discussion by any means even when we are talking about the addition of only two new components. So, your obtaining an understanding is not going to be achieved at one sitting in front of the "definitive" posting to a thread.

One problem of seeking the "definitive" posting is that it cannot be born from a broken premise that article you were trying to figure out is lame in the extreme. Given everything you have revealed about it, it didn't present a solution to its fantasy antenna. That is why this work of fiction is not understandable.

73's
Richard Clark, KB7QHC

kek

just throw a wire out the window, plug it in, and see if it works!
ANY antenna connected with a hunk of hookup wire will work better than
NO antenna with a perfectly designed match!

A lot there, but I didn't get anything out of it.
At resonance, does the tank look capacitive, inductive, resistive, or all
>>to the antenna<< you connect to it. (this makes the assumption attaching
the antenna didn't change anything, it did, let's say I adjusted back to
resonance)
And then my original question,
Are you saying it is pure R at resonance?
A yes or no will be fine, then I can try to reprocess the above that
didn't get anything out of.

I'll bite,
I want maximum transfer of power, I'm still working with the tank as
a large pure R so I want the antenna to look like the same large R.
I realize there is still capacitance from the antenna to deal with.
Now are getting to conjugate :-)

Because of the wavelength of the BCB antennas are usually short and
capacitive,
so simple tuning with a single series cap works. The problem begins when you
tune to the high end of the band and you have to much capacitance to get to
resonance with your tank. Then the inductor can be added parallel to the
series
antenna tuning cap. Alternately and you could increase the tank inductor
size.

I didn't rewrite the whole article here, there was a solution
with three equations, that, using the antenna finds the L with the
constrants
of highest operating frequency and lowest capacitance of your capacitor,
then a program is run that finds values for C (antenna) and C (tank) and
I'm not ready to go here yet C (load), he also tunes the diode/earphone
load for optimum with yet another capacitor.
The funs over for now go to get ready for work,
Thanks, Mikek
PS, he runs the program with another, what you call fantasy antenna,
and I agree...

No you don't.

What you want is the lightest final load sufficient to drive a speaker for a detectable sound matched to the Tank such that it does not degrade its Q which in turn is the highest possible value for supporting the largest amount of signal from the antenna at hand.

Am I wrong?

We haven't got to the load yet! it's coming :-)

> for a detectable sound matched to the Tank such that it does not

> supporting the largest amount of signal from the antenna at hand.
>
> Am I wrong?

There is a chance the Q (loaded) will be high enough to limit audio
bandwidth.
So (I think) we couple more energy into the tank for more signal and this
would
lower Q for a wider bandwidth.

Here's a question I have brewing.

I have three circuits to put together, a source, a tank and, a load.
I have two scenerios. hmm..seems as though I have three!
For now assume they are all resistive.
These are all set up for maximum power transfer, just in different order.

Scenerio 1.
Let's say the tank is 1 megohm.
I drive the tank with a 1meg source, so now I have 500Kohm circuit
impedance.
Then I load this with 500Kohm load.
So..
The 1 megohm tank is loaded with 333,333ohms, 1meg//500k
The 1 meg antenna is loaded with 333,333ohms, 1meg//500k
The 500Kohm load is drive by 500kohms. 1meg//1meg

Scenerio 2.
1 megohm tank.
I put a 1 megohm load
I can drive the tank with a 500Kohm source,

So..
The 1 megohm tank is loaded with 333,333ohms, 500k//1meg
The 500 Kohm antenna is loaded with 500Kohms, 1meg//1meg
The 1 megohm load is driven by 500kohms. 1meg//500k

Scenerio 3.
1 megohm tankThe
I drive the tank with 2 megohm source and load it with a 2 megohm load.
So..
The 1 megohm tank is loaded with 1 Mohm, 2Mohm//2Mohm
The 2 meg antenna is loaded with 666,666 ohms, 1meg//2meg
2 megohm load is drive by 666,666 ohms. 1meg//2meg

I have no clue where maximum power is delivered
from the antenna to the load.

This aught to be fun :-)
Mikek

Hi John,

I do not understand where your -2947j figure comes from. I see it appearing
nowhere in my calculations.

The antenna mentioned by Mikek has an impedance of 58R-1,072j which, according
to my spreadsheet, corresponds (at 1 MHz) to the parallel of 19862R and -1075j
(that is a 148,1 pF capacitor).

In any case, parallel <--> series trasformations never result in a change of the
reactance sign; therefore it is not possible that a -2957j (negative) reactance
is transformed into a +2948j (positive) reactance.

Well, it's not mine and it appears in you post as 54 pF. Isn't 58R in
series with 54 pF equal to 58-2947j? And isn't the parallel equivalent
of that equal to 149k ohms of resistance in parallel with -2948 ohms of
reactance (~54 pF)?

I'm pointing out that you slipped a decimal point or you would have seen
that 54 pF is too much it results in the parallel equivalent resistance
of 149k rather than 1.49M. Mike's figure of about 18 pF (17 pF series
combination) will do the job.

You are correct. I allowed the sign of the suseptance to creep through.

Yes, at one o' clock in the morning, I slipped the decimal point. So, the total antenna series capacitance should have been about 17 pF, not 54 pF. This requires putting a 19-pF capacitance in series with the antenna, not 85 pF.

And the inductance resonating the residual parallel capacitance becomes 1,490 uH instead of 470 uH.

Sorry for mistake!

73

Hasn't anyone pointed out that this a problem made for using a Smith
Chart?

(Since no one really seems capable of doing the math :-)

Hi Mike,

How? (It would be a sad day for us all if more input to a Tank
lowered its Q were true.)

>Here's a question I have brewing.
>
>I have three circuits to put together, a source, a tank and, a load.
>I have two scenerios. hmm..seems as though I have three!
>For now assume they are all resistive.
> These are all set up for maximum power transfer

Actually, that remains to be seen. We must first establish that we
have the same available power in all three which I will give the
arbitrary value of 1 to simplify the math. Also, you mix your source
loading in these models, so in the sense of Norton/Thevenin sources I
describe the power being supplied by a parallel current source to keep
the units uniform.

>Scenerio 1.
>Let's say the tank is 1 megohm.
>I drive the tank with a 1meg source, so now I have 500Kohm circuit
>impedance.

This presumes a parallel current source by your description of the
input and tank appearing as a 500K circuit. This is why set the
initial condition of there being a current source for all scenarios.

>Then I load this with 500Kohm load.

The parallel current source then sees 250K Ohm for the same power
available to all scenarios.

```
     Pavailable = 1 = i��250K
     i = sqrt(1/250K)
```

As the current does not divide evenly, then we will work to find the
power to the load through voltage sharing. Obviously, there is the
same voltage across the three components, hence:

```
     e = i�250K = 500
     Pload = e�/500K = 0.50
```

>Scenerio 2.
>1 megohm tank.
>I put a 1 megohm load
>I can drive the tank with a 500Kohm source,

This does not qualify either a parallel current nor series voltage
source, but as both are fungible to design with the same value
resistance, then I will proceed as before with all three resistors in
parallel to a parallel current source:

```
     Pavailable = 1 = i��250K
     i = sqrt(1/250K)
```

Obviously, there is the same voltage across the three components,
hence:

```
     e = i�250K = 500
     Pload = e�/1000K = 0.25
```

>Scenerio 3.
>1 megohm tankThe
>I drive the tank with 2 megohm source and load it with a 2 megohm load.
>So..

This does not qualify either a parallel current nor series voltage
source, but as both are fungible to design with the same value
resistance, then I will proceed as before with all three resistors in
parallel to a parallel current source:

```
     Pavailable = 1 = i��500K
     i = sqrt(1/500K)
```

Obviously, there is the same voltage across the three components,
hence:

```
     e = i�500K = 707
     Pload = e�/2000K = 0.25
```

>I have no clue where maximum power is delivered
>from the antenna to the load.

Any clues now? Barring any math or conceptual error on my part, then
by one account more power (that is one measure of success) is
delivered to the load when its resistance is lowest.

How does this impact design priorities?

My thought was, if we couple more energy from the antenna, it loads
the tank more lowering Q. The thought might need more work....

 Scenerio 1 is how I have always thought about the system.
Nice to know where max power transfer is.

> How does this impact design priorities?

I'm still at design highest Q tank circuit then transform antenna
to match Z of tank. That's about as I want to go for now.
Not ready to get into that diode thing again.
Unless you've been studying :-)
running for cover.....
            Thanks, Mikek

   Well, that is nominally considered as "matching" in that the coupling
from the antenna is minimal so as to not load the parallel resonant
circuit; a tradeoff actually between energy transfer and loading.
   A better way might be to have a low Z tap on the inductor; a method
used in radios since the 60's i think.

   Yes that can be done, but my inductor will be 660/46 litz wire.
I'm sure it's possible to make a tap, but with the cost of litz I don't
want to.
           Mikek

Does anyone have any idea where I can obtain a replacement antenna for
an obsolete Icom ICA20 air band hand held radio, I've made a couple
myself but they're not cosmetically brilliant (!)   The IA20 bit
might not mean a lot in the "States" but the rig covers the VOR band,
and then 118 - 136 MHz AM.
The termination is BNC.

Thankx guys

Phil

google me this:
rubberduck antenna replacement bnc
```

go through till you find one that looks like it covers the bands you
want.

an example:
http://www.scannermaster.com/All_Band_Rubber_Duck_Portable_BNC_Antenna_p/10=
-540710.htm

```

I guess you want to transmit?

I found this one, but not too sure if its suitable for transmitting.

Thank you Tony, for the good description you made.
I wrote a short basic program to calculate the parallel conversion.
I can run the numbers for different frequencies, and different Cs and Rs for the antenna.
Thanks for the tip about the parallel inductor.
Thanks again, Mikek

just put it up, hook up a tuner if the radio doesn't have one, and have fun. you can spend all your time modeling trying to figure out what it may look like, but if you are limited on how you can install it you can't really control much anyway. an antenna laying on the ground works much better than one that is only in your computer!

No argument from me! It is going up as planned as soon as the new
General gets a little more time to work with me on the project.

The hillside we are working on is a little tricky for us to deal with
while snow covered but in this part of North Carolina it does not snow
often or stay long.

We need to keep his enthusiasm up with some positive results.

Archive-name: radio/ham-radio/moderated/crossposting
Revision: 1.1 2009/04/12 19:42:04
Posting-Frequency: posted monthly
URL: http://www.panix.com/~rram/usenet/rram/index.html

Changes followed by "|".

After a 30-day public discussion and feedback period to gauge reader opinions in March of 2009:

http://groups.google.com/group/rec.radio.amateur.moderated/browse_thread/thread/d7d337db35f23326

the rec.radio.amateur.moderated Moderation Team has decided to consider amending its charter, and permit limited simultaneous crossposting to rec.radio.amateur.moderated and one other unmoderated amateur-radio-related discussion newsgroup. We are currently trying this on a temporary basis (90 days, through early July 2009), and adopt it permanently if successful.

Approved rec.radio.amateur.* newsgroups are those that are currently listed in the latest version of the "List of Big Eight Newsgroups" which is crossposted monthly to news.announce.newgroups, news.groups, and news.lists.misc.

Approved alt.radio.amateur.* and alt.ham-radio.* newsgroups are those that have been created consistent with the suggestions in "So You Want to Create an Alt Newsgroup" at:

  http://www.faqs.org/faqs/alt-creation-guide/

Approved regional hierarchy newsgroups are those that contain either "radio.amateur" or "ham-radio" in their names, including uk.radio.amateur and aus.radio.amateur.misc.

We will make every reasonable effort to keep our list of approved newsgroups up-to-date. In case we have overlooked any, and a submission is rejected in error as a result, the rejected submitter can E-mail us at our administrative contact address (in the signature at the bottom of this article, and the default Reply-To for the rejection message) requesting that it be added, and that the article be approved. We may still choose to reject articles crossposted to any alt.* newsgroup with an inappropriate name, including obscene language, embedded name-calling, or encouragement of unlawful conduct.

Please direct any comments, questions, or criticisms to rec-radio-amateur-moderated-request@panix.com.

>you have a poor search engine, i get 6M hits... and all of them are
either for 'electric field' or 'electromagnetic wave'. provide a
formula or specific reference.

Write: ("electric wave equation") and your search engine will be poor.

For EM waves: "Maxwell's contribution to science in producing these equations lies in the correction he made to Amp�re's circuital law in his 1861 paper On Physical Lines of Force. He added the displacement current term to Amp�re's circuital law and this enabled him to derive the electromagnetic wave equation in his later 1865 paper A Dynamical Theory of the Electromagnetic Field and demonstrate the fact that light is an electromagnetic wave".

And:

"Heaviside worked to eliminate the potentials (electric potential and magnetic potential) that Maxwell had used as the central concepts in his equations;[21] this effort was somewhat controversial,[25] though it was understood by 1884 that the potentials must propagate at the speed of light like the fields, unlike the concept of instantaneous action-at-a-distance like the then conception of gravitational potential.[22] Modern analysis of, for example, radio antennas, makes full use of Maxwell's vector and scalar potentials to separate the variables, a common technique used in formulating the solutions of differential equations. However the potentials can be introduced by algebraic manipulation of the four fundamental equations."

Electric waves are normal pressure waves. In place of pressure is the voltage. In Heaviside's no voltage. But "However the potentials can be introduced by algebraic manipulation of the four fundamental equations."

Nice manipulations.
S*

> Electric waves are normal pressure waves. In place of pressure is the
> voltage.

sorry, this is not correct. site a CURRENT source for this
statement. you did a good job quoting the proper relations between
potentials and fields, why not for 'electric waves'? if there are so
many good references that your search shows up there must be one that
provides a current good description of them.

> In Heaviside's no voltage. But "However the potentials can be
> introduced by algebraic manipulation of the four fundamental equations."

of course, potentials are not required, they are a figment of the
equations. what is required are the fields. the potentials, as you
quote:

> Modern analysis of,
> for example, radio antennas, makes full use of Maxwell's vector and scalar
> potentials to separate the variables, a common technique used in formulating
> the solutions of differential equations.

are just a 'technique' used to solve the equations, they are not the
result. there are many techniques like that used to solve
differential equations, they often introduce new variables that have
no physical meaning but are useful to simplify the equations leading
to a useful result. as you quoted above, even heaviside realized the
potentials and therefore the separate electric and magnetic 'waves'
were not necessary to the solution so he eliminated them. while this
may have provided a simpler representation of Maxwell's equations, it
did not change the results that they represented.

In Maxwell's time were math for the longitudinal waves. I am sure that were
such for electric waves also. But I am not interested in equations.
Maxwell did the math for the rotational oscillations. It is still in use in
engines area.

What Heaviside did I do not know because I do not understand in what way the
magnetic whirl appears around the wire.
It is only the piece to teach the math.

The topic is if the damped radio waves exhibit "redshift" with the distance.

Well that just sucks!  I was relying on plasma technology to accurately
resolve LBW appeals.  What a complete bastard!!

No, the topic that you asked about is do sidebands change with distance.

But, yes radio waves do experience Doppler shift, damped or otherwise!

no, damped waves do not exhibit redshift with distance, unless of
course they are from a distant galaxy that is moving away from us
rapidly!

One sideband is "redshifted" and the second "blueshifted". AM waves have the
increasing/decreasing amplitudes. The damped also but there no symmetry.
Were the sidebands symmetric at the damped waves?
>
> But, yes radio waves do experience Doppler shift, damped or otherwise!

It is not distance dependent.

Seperate "electric field", "magnetic field", gravity field" are for kids.

Charged body at rest produces the electric field but a moving body do not
produce the electric field but magnetic.

Do you understand it?

> Maxwell did math for lots of
things unrelated to electromagnetics, that was a very interesting

>no, damped waves do not exhibit redshift with distance, unless of
course they are from a distant galaxy that is moving away from us
rapidly!

Wiki wrote: "They initially interpreted these redshifts and blue shifts as
due solely to the Doppler effect, but later Hubble discovered a rough
correlation between the increasing redshifts and the increasing distance of
galaxies. Theorists almost immediately realized that these observations
could be explained by a different mechanism for producing redshifts.
Hubble's law of the correlation between redshifts and distances is required
by models of cosmology derived from general relativity that have a metric
expansion of space.[16] As a result, photons propagating through the
expanding space are stretched, creating the cosmological redshift."

Photons are stretched with the distance.
Damped waves are like photons.

of course, that is why you haven't learned enough to understand them
```

that way yet, you are below kids in understanding fields.

do you understand that the electric field from a charged body at rest
does not propagate, it is static everywhere so there are no waves.

but what about if the body is at rest in one inertial frame and you
are moving past it in another one, do you see a magnetic field or
not?

now that is a good laugh... stretching photons would be quite a trick since they don't exist in Maxwell's equations. damped waves may be made of many photons, but they are not 'like' photons... they are just another set of em waves propagating along just like any other.

The only trouble for kids to remembe are the "hand rules".
Kids do not try to understand. They must remember.
Good memeory is most important in schools.

But in antennas charge appears and disappears. Electric waves must appear.
Some Authors call them electrostatic waves.

No. No magnetic charge and no magnetic field.

The "hand rules" were invented to be a memory aid, and that is all they
are, a memory aid.

Reposting the same shit in French does not make it applicable to EM radiation.

You are a babbling idiot.

"Waves in plasmas can be classified as electromagnetic or electrostatic
according to whether or not there is an oscillating magnetic field. Applying
Faraday's law of induction to plane waves, we find , implying that an
electrostatic wave must be purely longitudinal. An electromagnetic wave, in
contrast, must have a transverse component, but may also be partially
longitudinal. From: http://en.wikipedia.org/wiki/Waves_in_plasmas

In space is the rare plasma + dust.

Babbling nonsense.

Most of space is empty vacuum and "waves in plasma" has absolutely nothing
to do with real antennas, either on Earth or in space.

Hi - I'm an amateur radio newbie - don't even have a license yet (taking the
Technician exam 1/15). I have a Kenwood TH-F6A and I'm looking for an
antenna for use from home. This looks like a good one - and it's in my price
range ;-) I'm wondering what you experts think of it for a beginner?

http://www.diamondantenna.net/d130j.html

Also, I thought this might make a good mobile antenna. But the instructions
say don't use a magnetic mount. I'm really not interested in any kind of
permanent mount. Why do they say not to use a magnetic mount?

http://www.diamondantenna.net/d220.html

Thanks in advance for taking the time to answer.

In plasma are electrons and ions. Like in metals.

Tesla known that:  http://www.tfcbooks.com/tesla/1929-09-22.htm

":Up to 1896, however, I did not succeed in obtaining a positive
experimental proof of the existence of such a medium.  But in that year I
brought out a new form of vacuum tube capable of being charged to any
desired potential, and operated it with effective pressures of about
4,000,000 volts.  I produced cathodic and other rays of transcending
intensity.  The effects, according to my view, were due to minute particles
of matter carrying enormous electrical charges, which, for want of a better
name, I designated as matter not further decomposable.  Subsequently those
particles were called electrons."

You are still before the electron time:

 ""When Dr. Heinrich Hertz undertook his experiments from 1887 to 1889 his
object was to demonstrate a theory postulating a medium filling all space,
called the ether, which was structureless, of inconceivable tenuity and yet
solid and possessed of rigidity incomparably greater than that of the
hardest steel.  He obtained certain results and the whole world acclaimed
them as an experimental verification of that cherished theory.  But in
reality what he observed tended to prove just its fallacy".

But you are fine. Nothing wrong.

Hi Richard,

Leave it at unconventional - that word's definition is well understood.

>3. The relative field radiated by a conventional 1/4-wave vertical
>monopole
>driven against a perfectly conducting ground plane always is maximum
>in the
>horizontal plane. Such a system radiates virtually 100% of the matched
>power
>applied to its input terminals.

This reveals a common flaw found in vertical antenna analysis when compared to AM antenna measurement conventions. Simply put, if you lift the antenna off of an infinite plane, you lose 3dB. It is demonstrable with even the meagerest of antenna modelers.

Chip's antenna is in the air, not on an infinite plane. A solid disk replacing a field of radials does NOT constitute a replacement for an infinite plane such as to recover the 3dB. This might account for the bookkeeping error in the vendor's favor.

I believe somewhere in the tightly scripted presentation it was asserted that there was no "figure 8" pattern as one would expect of an antenna in free space.

The antenna is "apparently" in an anechoic chamber - or free space as closely as can be approximated. There are no reports of the far field envelope shape.

So let's mark it up to Chip's usual technique of loose suggestion
being passed off as a citation to then be wrapped back as a proof.

>Therefore the peak gain of that antenna system at resonance cannot be
>improved
>by putting a sleeve of any kind on the monopole.

I would dispute that. The evidence is sufficient insofar as the
indication of change in the before/after display on instrumentation.
Unless this is some form of parsing what "peak gain" means. What you
write immediately following already conforms to that instrument
display:
>
>The sleeve may change the shape of the radiation pattern of the system
>without
>the sleeve, though, which could change the field intensity at the
>location of
>the receiving antenna used in the test. This could account for the ~3
>dB
>improvement shown in their results when using the sleeve.

And by what you say above, this is the entirety of it. A thicker
radiator - nothing less than has been covered in text for decades. You
observe that below.

>4. Nothing is shown in the video about the amount of matched power at
>the
>feedpoint with and without the sleeve. If that is not held constant
>then the
>test will be flawed.

The instrumentation already takes care of that, and is discussed early
in the presentation. I was doing this kind of bench work, with this
kind of instrumentation, in this band, 20 years ago.

>5. The VSWR bandwidth of a monopole may be increased simply by using a
>larger
>cross-section conductor of "non-fractal" construction.

Of course - but that information doesn't sell product.

Hi Ron,

Welcome to the possibly the last vestige of Amateur Radio hardware experimentation.

Insofar as your antenna goes, it presents you with a learning opportunity that far exceeds the material you will be tested for. However, it does embody the significant first principles.

1. The correlation between physical size and wavelength.
2. The discussion of match.
3. Unfortunately it says nothing of the radiation pattern which has very serious implications for use.

Let's return to item 1 and examine the antenna. The overall height can be rounded to 2 meters for simplicity's sake (there is no reason to be exact and this is sufficiently accurate enough for the moment). Your coax connection goes somewhere near the middle of the structure to make it a dipole - a vertical dipole of unusual shape, but still within the terms of first principles, a dipole.

This makes it suitable for use on the 4M band by simple correlation between size and wavelength. However, there is no 4M amateur band, and the vendor claims down to 10M and below.

The paragraph above marks our transition in the discussion towards match. By virtue of its shape (its unusual shape), it benefits from being a match at frequencies that are outside of its 4M native band. This is true for the frequencies on BOTH sides of this band. The long and short of it is that YES, the antenna is a suitable load over the entire range of frequencies, and this is of high interest to any Ham.

However, being a suitable load to your transmitter (the antenna matching the transmitter's requirement for a particular size value, often 50 Ohms resistive with little or no reactance) is only half of what interests any Ham. The other half is how well does it radiate towards my intended listener?

This brings us to item 3 listed above. At the lower frequencies (below 2M band), you can well allow that you will obtain a lack-luster performance. This antenna design is suited for multiband operation which sacrifices gain opportunity to achieve it. This is the see-saw of antenna design - and you choose what is most important at the cost to the other issues.

Further to item 3 is the fact that above the 2M band this antenna might well seriously disappoint. This is a first-pass observation, but on close examination, you have selected an antenna that is actually two in one. Look closely at the two distinct sets of spoking elements. The lower flaring down are chosen for the lower band, the upper, more horizontal are chosen for higher bands - such as 2M and 440. The antenna has been optimized to recover from the see-saw of conflicting choice (we ALL want an antenna with universal coverage and maximum gain knowing we can not have both, and worse, we can barely expect half than less).

Still, even with this hail Mary pass, above 440 the antenna is going to be a very poor performer in getting signal out towards the horizon (where your listener might be), and instead put it up into the air (where no one is, except satellites, model rockets, and airplanes).

So, this being a brief discussion (some might argue otherwise), more is left to be said in response to all the questions it might provoke.

>Also, I thought this might make a good mobile antenna. But the instructions
>say don't use a magnetic mount. I'm really not interested in any kind of
>permanent mount. Why do they say not to use a magnetic mount?
>
>http://www.diamondantenna.net/d220.html

Wind force and moment arm. It is a LOT of wire in the air for highway speeds. Trust the instructions.

He is using a resonator to drive another radiater
(see constant impedance antenna system patent) The radiator that he
is driving is of multiple wavelength as in a wire mesh where the
multiple routes that can be taken by current flow provides an ultra
wide frequency span as the reactance changes become smaller and
smaller.
The final radiator is a full wave or more closed circuit version which
provides more gain than a fractional length over a ground plane
Very simple use of a metamaterial which has been demonstrated in most
universities of the day.

Hello,

Have a new WinRadio receiver, and am a bit concerned about protecting it's front end from possible damage due to ESD ElectroStatic Discharge, effects, etc.

I do receiving only, and have an end-fed PAR antenna outside, feeding the receiver by about a 30 foot run of coax from the antenna.
At the antenna, I have an ICE lightning protector, and a copper bar as a ground point, there.

No idea if the ICE unit has a bleed resistor for dissipating any static buildups.

Too advanced in years now to build anything myself incorporating Zeners, Varistors, or whatever, so would like to find, if you folks feel it's worth doing (?), a small box unit with bnc's on both end, that would provide good and safe ESD protection that I would locate indoors right next to the radio's input.

Any thoughts or suggestions ?
Brand, Model Number, or just forget as probably not needed ?

BTW: Nice article on ESD at:
       http://www.ce-mag.com/archive/01/Spring/Lee.html

Thanks,
Bob

Free electrons in a vacuum are nothing like a plasma.

Free electrons in a vacuum are nothing like metal.

Yep, they were all wrong; there is no "ether".

What most folks do is put Back to Back diodes, across the 50 Ohm input,
and that clamps the antenna input to .7 Vac before the diodes conduct.
You may have to replace the diodes if you get a discharge, but not until.

Hi Richard,

Thanks for the detailed response. The Kenwood TH-F6A radio I intend to use this antenna with is a handheld with 5W max output power. It is a 2m, 1.25m and 70cm transceiver, with a separate wideband, all mode receiver built in that has a capability from 0.1 - ~1300 MHz.

http://www.kenwoodusa.com/Communications/Amateur_Radio/Portables/TH-F6A

With that in mind, what is your opinion of the adequacy of this antenna?

Thanks, I thought that might be the case. Again, keeping in mind the radio I intend to use, would this antenna be a good fit?

Ron Hinds

>Thanks for the detailed response. The Kenwood TH-F6A radio I intend to use this antenna with is a handheld with 5W max output power. It is a 2m, 1.25m and 70cm transceiver, with a separate wideband, all mode receiver built in that has a capability from 0.1 - ~1300 MHz.
>
>http://www.kenwoodusa.com/Communications/Amateur_Radio/Portables/TH-F6A

Hi Ron,

Generally speaking, the more functionality, the more tepid the utility. However, as a 2m, 1.25m and 70cm transceiver paired with the antenna you describe, you will have every opportunity to do quite well. What could improve things? Raise the antenna higher! (No matter how high it might be.) This is, after all, line-of-sight operation. I can get into my buddy's 2M repeater 10 miles away, from my basement with 125mW into an HT antenna; others that are closer have to step out onto their back porch.

>With that in mind, what is your opinion of the adequacy of this antenna?

Above the 70cm band it is going to be deaf.

As I introduced my last response, this forum's best participation comes through experimentation and construction. You could easily and cheaply build your own 2m, 1.25m and 70cm transceiver antenna(s). The difficult part may be in making them robust, or building something similar as multi-band - nevertheless, building one that is adequate takes no more than a simple SO-238 socket and five pieces of heavy copper wire. A more elaborate one would have more wire and would challenge you for insuring its robustness simply because you would have to brace the extra wire in what is called a Discone Antenna design.

The antenna you are contemplating is based on the Discone which is notable for being multiband and very simple (although too many websites mystify it - ask questions here).

Returning to the deafness above 70cm, this wavelength is verging on being so small, that it would be a sin NOT to build your own antenna for those high bands. This is something you can do at the kitchen table in an evening during commercial breaks.

Hi Ron,

Antenna design has many variables with frequency (or its inverse with wavelength) being key among them.

This means, of course, that you must first select the frequency or band of frequency you want to work (or to listen to).

Second, you would want to set some goal for gain over an ordinary dipole or monopole (a misnomer as all antennas are dipoler, but this term is universally acknowledge to informally mean a vertical). Perhaps a dipole or monopole (vertical) is enough to begin with.

Third, you want to select the polarization you intend to work (or listen to). This is extremely important for VHF/UHF because its line-of-sight path is very polarization sensitive. Verticals will "see" verticals. Horizontals will "see" horizontals. Verticals and Horizontals will be blind to each other. This is sort of mixing metaphors where previously I used the term "deaf," it amounts to the same thing: "cross polarized" signals will NOT WORK. In the VHF/UHF bands, casual use is vertical polarization; however, for serious DXers it is often horizontal and that activity is usually confined to DX bands within the VHF/UHF. By casual use I mean simplex between you and someone else locally, or contacts through repeaters for greater, but still local range.

Fourth, height is key to "seeing." And, as you are entering into experimentation, you want to erect some pole that will be both securely fastened when erected, but also lowerable so that you can attach your design and transmission line to it. Here again is the see-saw nature of design. You will be raising and lowering this more than once, so plan on it ahead.

Fifth, once you have the first four thought through (if not actually achieved) you should observe one quality about antenna design: it is scaleable. This means that if you find an antenna described on the internet that embodies all of the considerations listed above BUT it is in the wrong band, then there is a simple solution. An example will serve to illustrate.

Let's suppose you run across a Discone Antenna design on the internet (it satisfies your need for multiband application, let's say). However, the author of the design reveals how it was set up for HF operation between 60M and 10M (a very do-able design, if somewhat unwieldy in construction). Your interest is not in HF (suppose), but rather in VHF. What to do?

The antenna you are considering, but which is too large, is too large by 10 times. Scaleability in antenna design answers this with: change the existing design to 1/10th of all physical lengths and widths.

TA DA! A broadband antenna that works 6M to 220MHz with the characteristics of the original size. What was formerly an unwieldy size is now more manageable by virtue of scaling.

Just do it.

The same logic applies to more complex designs (and less complex ones, certainly) that you might see touted on the internet.

Finally - there is no reason to expect that anything you find on the internet actually works as the author of the page may describe. In fact, the higher the content of gushing and exhortation, accompanied with a laundry list of claims, will give every indication of someone being out to lunch. Check in here for sanity checks. This may inspire long discussions that ramble through many posters here (so far, none have been inspired to dip their oar in this thread). This is the nature of newsgroup activity that often focuses on minutia. However, from the bulk of response, you will get the general sense.

Well there's always thru-the-glass. It's not the most efficient in my experience (which is limited with respect to these) but it seems to work well enough if you have a decent repeater system that is the target. One plus is that you can usually get most of the half wave above the roofline.

For all around flexibility I still like the simple quarter wave vertical for 2m FM. Enough high angle for metro downtown use, but that involves either holes or magnets.

Richard is providing a lot more info than me, but the reality is this:
5 watts is not going to do all that great. Your mileage may vary, but
a lot of that power will be eaten up by feedline losses.

Also, bear in mind that a multi band antenna is generally a compromise
on every band it works on.

And finally, a hundred bucks plus shipping is a ripoff for that
antenna in terms of performance. On 2 meters, 220, and 440 a jpole you
could make out of old curtain rods or scrap conduit for ZERO will work
as well or better.

Also, if you make antennas...do not just clone something. 75% of jpole
projects start with copper tubing you have to purchase. Nothing wrong
with that, but the reality is anything metal you can make long enough
will likely work fine. Most people who publish web how to's on Jpole
antennas are copying old designs. Designs get set in the mud and dry
```

out to the point that noobs get a mindset that nothing else can work
on account of seeing so much of the same thing.

A hundred bucks would go a long way toward some high quality feedline.
Save the money and build an antenna.

Dave

```

Does the radio have any coils in the front end? Like the old-time radios, a=
 primary coil between the antenna and chassis ground. If it has coils, ther=
e is NO way for static electricity to build up beyond millivolts, since all=
 is at DC ground.=20

Diodes and other devices across the input are invitations for disaster. The=
y ALL fail open circuit, leaving the device available for destruction by ne=
xt charge.

If you put anything across the antenna input, use an RF choke. At least whe=
n it goes, you will smell smoke.

My main antenna is a 160 meter horizontal loop up 35 feet. Fed with 125 ft.=

 of 600 ohm feed line. The feed line connects to the internal balun in an a=
ntenna tuner which keeps the shack end of the antenna at ground potential. =
If I disconnect the feed line during an active thunder storm, I can immedia=
tely draw an arc of at least 1/4 inch. So, I leave all hooked up unless I s=
witch the feed line directly to the shack ground. I have never had an ESD p=
roblem coming via the antenna, and I don't think you will either.

Paul, KD7HB

unless the radio was shipped to you in a sealed esd protection bag and had notes about what the esd handling requirements were, forget about it and just plug it in and use it! ESD problems normally only apply to bare integrated circuit leads and things connected to them like pins on a card plugging into a computer motherboard. anything on an external connector like where you would connect power and antennas should already have sufficient protection for normal use.

My older Element had plastic covers over the mounts for the roof rack.
Perhaps you can mount the antenna to the same brackets.

Hi Dave,

Thanks for your comments. On the subject of feed line - which of these would
be better:

RG-8X
RG-8/U
RG-213/U

Thanks again for the reply.

- Ron

RG-213 and RG-8 (both of which standards are actually obsolete, so you're buying RG-213 "type" cables) are basically the same.. roughly 0.4" in diameter, solid polyethylene dielectric, AWG13 inner conductor.

RG-8X is a smaller diameter foam dielectric cable which will have higher loss (because the conductors are physically smaller, so IR losses are higher).

There are tons and tons of other cables that may be better or worse for your application.

Are you looking for something for VHF and up? In that case, the foam dielectrics tend to be lower loss than the solid dielectric. foam dielectric 75 ohm coax (as used in cable TV systems) is pretty good from a loss standpoint at VHF and UHF, although you need to check the exact type (there are some pretty bad 75 ohm coaxes out there, too).

Do you care about exposure to the elements?
Does it need to be flexible?

Are you transmitting through it (e.g. is power handling important?)

Then of the three I mentioned, the RG-8/U would be best?

> There are tons and tons of other cables that may be better or worse for your application.

Yes, I am mostly interested in 2m, 1.25m, amd 70cm at the moment. Most cables I've seen - in my admittedly brief exposure - have been 50 ohm. Wouldn't 75 ohm cause more loss?

> Do you care about exposure to the elements?

Yes, as it will be running from a roof antenna to the house. It is on the north side of the building though, so the majority of it would not be exposed to the sun.

> Does it need to be flexible?

Somewhat. Once in place it won't be moved around much, if at all.

> Are you transmitting through it (e.g. is power handling important?)

I hope to be ;-) I'm taking the Technician Class test Saturday! As for power handling, all I have at the moment is a 5 watt max handheld. I am interested in building a 50-100 watt power amp for it, though. You wouldn't happen to know where I could find a schematic for such an animal, would you? Thanks so much for your reply Jim!

Ron Hinds wrote:
> Then of the three I mentioned, the RG-8/U would be best?

I think you have completely lost sight of what you are doing. The radio in question is a handheld device, aka a "Handie-Talkie" or H/T. It is designed to work with the whip antenna that comes with it.

It may not get better reception or transmission with a larger antenna, and may actually do worse. The front end of the radio is not designed to handle large signals and it could easily overload and hear nothing.

Obvioulsy an outside antenna is needed if you are inside metal or poured concrete (due to the steel reinforcing bars) walls or in a car. In a wooden or plasterboard house, you may not get a lot of improvement nor need it.

You might think that a high gain antenna will improve your reception, but if there is a close station or repeater it will just blank out. It does not have to a ham transmitter, paging, VHF (fire/EMS, etc) will wipe out 2m, and UHF can disappear under a GMRS or land mobile system.

If you live out in the woods, then a decent outside antenna will help and
a random wire or dipole will help with HF reception. In a big city, the
ferrite bar (up to 7mHz) will be a noise magnet and you many not even be able
to receive anything at all.

As for coax, good quality RG-6 coax will do fine, and you can get it almost
anywhere. Make sure to use high quality COMPRESSION connectors and adaptors.
The radio uses an SMA connector so you will need to get an SMA to F to connect
it to the coax and the antenna will have a PL-259 (aka UHF) or "N" connector
on it so you will need to get the connectors from a specialty shop.

You also want to get an external speaker and microphone as if you connect
up a coax to it, you will destroy the radio. The stress on the antenna
connector will cause it to break, or crack the circuit board it is connected
to. If you epxect to hand hold the radio and talk on it, something stiff
such as RG/213 may not last out a day of activity. :-(

Geoff.

I saw a note from a guy who "cooked" part of his window with the thru-
the-glass approach.  He said the film sandwiched in the safety glass
darkened from being heated.  As I recall, he was using 50 watts.

This stuff is all trade-offs, eh?

Amen!

I love to build antennas and I could not do it without some form of measurement device to determine the characteristics of the in-work project. I usually go by VSWR and alter the design in various ways (often slight changes to element lengths) to minimize the VSWR at my chosen freq. a VHF/UHF VSWR meter can be had for peanuts but a 250-dollar antenna analyzer will be in your future if you get a case of Antenna Fever. (Yeah, I have one.) However, as you are just getting started, try reading this: http://kb6nu.com/no-vhf-swr-meter-no-problem/

I like working in copper pipe at VHF and above. It's very durable and responds well to a Home Depot propane torch for so-called "sweat soldering." Copper pipe comes in several grades. The cheapest grade seems to make antennas that are just fine.

Welcome to the hobby.

I always "pigtail" fat, stiff antenna cables if I'm using them on an HT. A pigtail is a short length of a small. lightweight cable that's sufficiently flexible to put no great strain on the HT connector. Since it's short, you don't lose significant signals. Some folks will claim that losses in the extra connectors and adapters are a big problem. Nope, not if they're properly made and installed.

Hi All,
 Please look at this in fixed font.
 I'm looking for understanding of a series to parallel conversion for antenna matching.
I'm pretty sure I'm missing something, so point it out to me.
This is in regard to a crystal radio, so the match is for a low impedance

antenna to a high impedance tank circuit.
The antenna: R=58 ohms C=1072 ohms at 1Mhz.
The tank: L=240uh C=106pf Q = 1000
Tank Z =~1.5 Mohms
Here's my understanding of what I think I'm reading.
I put a matching capacitor in series with the antenna.
Antenna--> -----R-----C--------Match cap-----tank------ground.
and this is supposed to transform the circuit to this.
(Maybe better said, equivalent to this)

```
                      l------------l
                      l            l
Antenna--->  R C        LC<---Tank
                      l            l
                      l------------l
                           ^
                      Ground
```

I calculate an 18.5pf cap for the match, making the antenna look like 58R and 17pf.

So this; Antenna--> -----58R-----270pf--------Match
cap18.5pf-----1.5Mohms------ground.
This converts to;

```
                        l-----------------l
                        l                 l
Antenna--->58R 17pf        1.5M<---LC Tank at
                        l                 l        Resonance
                        l-----------------l
                               ^
                          Ground
```

And I now have a 1.5 Mohms source feeding a 1.5 Mohm load.
The purpose of which is to cause minimal loading of the tank by the antenna.
I don't understand how adding a series capacitor makes a parallel conversion.
What do I misunderstand or do just need to believe the numbers.
Thanks, Mikek

Hi Mike,

Is this a fantasy antenna?

For the 58 Ohm resistive value, it would have to be about 300 feet tall - not the size of operation one usually comes to expect for a Xtal radio aficionado.

If it is that tall, it would exhibit 200 Ohms Inductive reactance (one fifth of what you report, and the opposite sign).

Something doesn't wash here.

>I calculate an 18.5pf cap for the match, making the antenna look like 58R
>and 17pf.

58�j17 Ohms is still a complex impedance, and says nothing of match which can only be expressed in terms of the expected load R.

>And I now have a 1.5 Mohms source feeding a 1.5 Mohm load.

How that is arrived at is something of a mystery. By the numbers, you describe a 26000:1 mismatch.

>The purpose of which is to cause minimal loading of the tank by the antenna.

Well, what you have described is sufficient mismatch to insure that. The English reading of your sentence also is instructive: the tank is isolated from the antenna, i.e. no signal is passed to it. This seems to be counterproductive in regards to detection.

> I don't understand how adding a series capacitor makes a parallel
>conversion.

Haven't we been down this road some months ago?

Perhaps it's a longwire antenna, of crappy wire, parallel to
the ground?

It's an example from an article, I don't like the number either, seems like
maybe
2 to 12 ohms would be more realistic. I think the capacitance is ok.

> For the 58 Ohm resistive value, it would have to be about 300 feet

Ok, how about just working with the concept.

>>I calculate an 18.5pf cap for the match, making the antenna look like 58R
>>and 17pf.
>
> 58�j17 Ohms is still a complex impedance, and says nothing of match
> which can only be expressed in terms of the expected load R.

Sorry, I missed a math step, the R was converted to 1.5M.
see formula below.

>>And I now have a 1.5 Mohms source feeding a 1.5 Mohm load.

> How that is arrived at is something of a mystery. By the numbers, you
> describe a 26000:1 mismatch.

Here's what is stated in the article:
" The concept is that at any given frequency, a parallel RC network has an equivalent
series RC network, and vise versa. We can use this property to transform the real component
of an impedance to a much higher or lower value.
As long as Xc series >> R series.
Xc (parallel) = Xc (series)
R (parallel) = XC^2 (series) / R (series)
The Xc of a 17pf at 1Mhz is 9368 Ohms.
To rewrite Rp= 9368^2 / R = 1.513 Mohms

The article then goes on to say,
The utility of this equivalence can be seen by choosing a sufficiently small value of C series
(a large Xc series) A "small" resistance can then be transformed into a "large" value.

>>The purpose of which is to cause minimal loading of the tank by the
>>antenna.

distance dependent than what broadcast radio is.

Here you are:

Look at the damped waves: http://en.wikipedia.org/wiki/Damped_wave

They are like the AM.

Next look at Mr. Russell's animation:
http://paws.kettering.edu/~drussell/Demos/Solitons/solitons.html

He wrote: "a.. The speed of the wave depends on the height of the wave."

The speed of the disturbance in media is the amplitude dependent - it is the physics law.

So I do not think. I am sure.
I only want you find out proper evidences. It should be interesting to you.

electromagnetic waves are not solitons.  speed of an em wave is not
amplitude dependent, that is a physics law.

I believe you are laboring under the false impression that mr.B is able to
think.

--
Jim Pennino

Yes. But EM waves are Heaviside's paper waves. In rality are Tesla's waves.
Do not be lazy and look for evidences.

i don't care if he can think, as long as he is mildly amusing.

There is no 'evidences' for that.  Maxwell's equations describe EM
waves perfectly well, have been verified by experiments for over 100
years, and work fine for me.

Only if it is modulation by a triangle wave and WAY over modulated, otherwise, no, it is not.

> Next look at Mr. Russell's animation:

> physics law.

Nope, not physics in this universe.

> So I do not think.

First thing you've ever said that makes sense.

> I am sure.

You left off the last part of the sentence: "a babbling idiot".

> I only want you find out proper evidences. It should be interesting to you.
> S*

"Interesting" is not a word I would use to describe your posts.

"Laughable", "deluded", and "babbling" come to mind.

Biot-Savart and Heaviside made the very simple model. So simple that it was
choosen to teach the math.
Read at 1825:

A_Brief_History_of_Electromagnetism.pdf

It is unfortunate that you do not know the electrDYNAMICS by Ampere and
Maxwell.
It should be interesting to you.
Maxwell did not write "Maxwell's equations".

Something about the whole site seems to ring alarm bells with me, right
from the similarity of the name to Ansoft to the Western Union payment
option!!

Jeff

Maxwell's equations include Ampere's law, Faraday's law, and Gauss's
law... so all the dynamics and statics are included.  According to my
history the set of 4 equations was first written by Maxwell in 1863,
though in a different form than they are customarily seen today.

similar, he was referring to an article on solitons which were first
observed on water... but which bear no resemblance to EM waves.

Ah, yes, the website that promoted the CFA while simultaneously warping
electromagnetic theory. But then I guess I just "don't understand".
Thanks, but I'll stick with ARRL pubs and ref books by Kraus, Jasik,
Terman, King & Harrison, et al for trusted, practical info on antennas.
  73s,

Your citation was the reason for me to think: "maybe it isn't NEC
based and is able to some other nice things". However when you look to
further info on the site, it looks wire based.  If it is capable of
using other basic elements/segments (for example flat strip), I would
expect some examples on their website.

> lots of nice words, and plenty of pretty pictures on their site... but
> i wonder how well verified it is.
```

Given the info on the web and the responses to my thread, I agree on your statement.

Best regards,

Wim

Because it's entertaining, often thought-provoking and never dull. I have no quarrels with the folks you mention and they can hold whatever views they wish; they are certainly capable of producing workable ham band antennas. The problem is the "procrustean bed" that is often used

to "fit" the theory to the antenna design. In the extreme it's the
difference between tinkering and hoping for an efficient, practical
solution vs. applying good engineering and science in coming up with a
viable implementation (which is why I mentioned those reference books in
my previous post). Sincerely, and 73s from N4GGO,

Hello Bill,

You did make yourself fully clear to me with your first reply, thanks
for that. If it is/was useful existing SW, I would expect at least
some info on the antennex site, without the need for creating a new
topic.

I expect that at least some users of antennex also follow this NG and
would respond if they know something about the ansof package.
Therefore I didn't started a new topic yet.

Hello John,

OT: There is info on EH, CFA and other fancy antennas on antennex, and
many other places. That doesn't make such places useless. I have dug
through many documents on antennex and there is lot's of useful info.

As with all "information", the difficulty is finding out whether the
"information" is useful for one's special situation. Some of my
favourite books: Kraus, Orfanidis, the services textbook of radio
volume 5, antenna engineering handbook (Johnson).

As usual, just a bunch of babbling nonsense.

The only thing interesting thing is the link which you obviously don't understand.

And he hasn't a clue that solitons require a medium to exist while EM does
not.

To him, an EM wave, a sound wave, a water wave, and a female member of the
Navy in 1944 are all the same thing.

similar, he was referring to an article on solitons which were first
observed on water... but which bear no resemblance to EM waves.

Yes. But it bear resemblance to ELECTRIC waves.

Well, I was there for most of the CFA "saga," and saw no such "promotion."
Instead, I watched the constant stream of challenges by both Jack Stone --
the publisher, and a host of others (including yours truly) that examined
the CFA from all angles and came to the same conclusion: The CFA is/was a
hoax based on the inventors's lack of understanding of EM theory.

All the best,

Bill Miller

Your citation was the reason for me to think: "maybe it isn't NEC
based and is able to some other nice things". However when you look to
further info on the site, it looks wire based. If it is capable of
using other basic elements/segments (for example flat strip), I would
expect some examples on their website.

> lots of nice words, and plenty of pretty pictures on their site... but

Given the info on the web and the responses to my thread, I agree on
your statement.

Best regards,

Wim

>Maxwell's equations include Ampere's law,

It has name "Amperes law". It is Biot-Savart law with the displacement
current added by Maxwell.

>Faraday's law, and Gauss's
law... so all the dynamics and statics are included. According to my
history the set of 4 equations was first written by Maxwell in 1863,
though in a different form than they are customarily seen today.

See: http://en.wikipedia.org/wiki/Maxwell's_equations

"Maxwell's equations are named after the Scottish physicist and
mathematician James Clerk Maxwell, since they are all found in a four-part
paper, On Physical Lines of Force, which he published between 1861 and 1862.
The mathematical form of the Lorentz force law also appeared in this paper."

" (As noted above, this terminology is not common: Modern references to the
term "Maxwell's equations" refer to the Heaviside restatements.)"

In Maxwell's paper were 20 equations to describe this model:
http://en.wikipedia.org/wiki/File:Molecular_Vortex_Model.jpg

There are the cross section of the magnetic lines of force. They rotate but
nothing is flowing along them. The rotations rotate the plane of light
polarisation inside of the solenoid.

In Heaviside's "restatement" something flow along the lines and they do not
rotate.

Take a glance at: http://en.wikisource.org/wiki/On_Physical_Lines_of_Force
Excelent English. Perfect physics.

This should be good...

Tell us what is an "electric wave" that isn't a part of an "elecromagnetic wave".

Oh goody, you can cut and paste from a web page.

Too bad you don't know what any of what you quoted means.

Pure, babbling, word salad gibberish.

The Moleculare Vortex Model refers to magnetic fields, not electromagnetic
fields and there is no light of any polarizatin inside a solenoid.

What a buffoon.

You haven't a clue what any of your referenced links mean.

not only that but the reference is an article from a magazine published years before the completed set of Maxwell's equations were first published. During those years there were many changes in the understanding of electricity and magnetism and EM waves... not that the initial publication of Maxwell's equations completely converted those who had different viewpoints, obviously aetherists and adherents to other old and disproved theories still exist despite 150 years of experiments that have failed to damage Maxwell's equations.

Hello, and yes, IIRC to his credit Mr. Stone did publish (later on) Dr.
John Belrose's "mythbusting" of the CFA. Who at antennex was demanding
performance measurements to substantiate the CFA's proponents' claims?
Did the quantity and duration of those CFA articles on the website
confer legitimacy and promotion? Did Mr. Stone transform from believer
to skeptic?   I wonder if antennex is at least in part more about
entertainment and tantalizing pseudo-science rather than reality. Like
a certain TV show starring two Roto-Rooter plumbers "ghost hunting" in
their spare(?) time. Hey, if you can't get valid measurements on your
test equipment just substitute melodramatics. 73s,

not only that but the reference is an article from a magazine published years before the completed set of Maxwell's equations were first published. During those years there were many changes in the understanding of electricity and magnetism and EM waves... not that the initial publication of Maxwell's equations completely converted those who had different viewpoints, obviously aetherists and adherents to other old and disproved theories still exist despite 150 years of experiments that have failed to damage Maxwell's equations.

See at this:
http://en.wikipedia.org/wiki/File:Commercial_Solenoid_Dawes_1920.png

There is shown the magnetic flux (Heaviside). Tell me which physical law produce it (the hand rule is not a physical law).

Now see at Maxwell's model:
http://en.wikipedia.org/wiki/File:Molecular_Vortex_Model.jpg

There the curent in the solenoid physically rotate the magnetic lines of force.

So " During those years there were many changes in the understanding of electricity and magnetism" and the hand rule becomes a physical law.

so you have taken 2 unrelated drawings without the explanatory text to
show what?

The 'hand rule' as you call it is not a physical law, it is a
convention that is used to easily remember relationships expressed in
higher mathematics. There is no magic or physical meaning to it... in
fact both 'hand rules' are used depending on how you learned your
electronics, as long as you are consistent the provide identical
results.

Maxwell model (page 304):
http://en.wikisource.org/wiki/On_Physical_Lines_of_Force
"Let the vertical circles V and V represent the molecular vortices of which
the line of magnetic force is the axis. V revolves as the hands of a watch,
and V the opposite way."

"We have thus obtained a point of view from which we may regard the relation
of an electric current to its lines of force as analogous to the relation of
a toothed wheel or rack to wheels which it drives."

>The 'hand rule' as you call it is not a physical law, it is a

convention that is used to easily remember relationships expressed in higher mathematics. There is no magic or physical meaning to it... in fact both 'hand rules' are used depending on how you learned your electronics, as long as you are consistent the provide identical results.

But what kind of force cause the magnetic flux?

In Part IV Maxwell wrote:
"Now it seems natural to suppose that all the direct effects of any cause which is itself of a longitudinal character, must be them- selves longitudinal, and that the direct effects of a rotatory cause must be themselves rotatory. A motion of translation along an axis cannot produce a rotation about' that axis unless it meets with some special mechanism, like that of a screw, which con- nects a motion in a given direction along the axis with a rotation in a given direction round it ; and a motion of rotation, though it may produce tension along the axis, cannot of itself produce a current in one direction along the axis rather than the other."

Does Heaviside's mechanism in form of the 'hand rule' "works fine for you."
EM is for kids. Are You?

EM is for kids?? i take it that you think EM is too simple and you
must have a more complicated theory? if that is so then i understand
why you are trying to study ancient research, back then there were
many competing theories each with separate complicated descriptions
about rotations and forces... all of those were made simple when
Maxwell combined the essential 4 equations to describe electromagnetic
interactions, add in ohms law and the Lorentz force equation and you
have everything necessary to describe EM effects... Sometimes simple
is best.

EM is is a simple version of Maxwell's model.

> if that is so then i understand
why you are trying to study ancient research, back then there were
many competing theories each with separate complicated descriptions
about rotations and forces... all of those were made simple when
Maxwell

It was Heaviside,

>combined the essential 4 equations to describe electromagnetic
interactions, add in ohms law and the Lorentz force equation and you
have everything necessary to describe EM effects... Sometimes simple
is best.

Maxwell's model and EM by Heaviside are not simple.
The most simple and the best is the gas (electron) analogy. All waves are
the same.

analogies are not theories, nor are any good at making predictions.
being able to predict things is required of theories, they must be
able to predict things that can be tested to either prove or disprove
the theory. an analogy is just a story trying to explain one thing as
if it were something else, this unfortunately doesn't work very well.

Maxwell's equations are very simple, that is what is best about them.
They have taken the absolute simplest set of equations necessary to
describe all electro-magnetic phenomena.

All babbling gibberish.

You never did address the question of what it is you think an "electric wave" is.

no, the 4 Maxwell equations are all that is necessary for propagation
in vacuum or other medium... its in there, you just have to learn how
to solve them properly.  if you are seeing bigger sets of equations
for em waves then you are reading something that is outdated.

you never did give the equation for an 'electric wave'... please
provide that.

you have a poor search engine, i get 6M hits... and all of them are
either for 'electric field' or 'electromagnetic wave'. provide a
formula or specific reference.

Xref: g2news2.google.com rec.radio.amateur.antenna:21891

I am helping to install a 135 foot dipole on a hillside for HF
activity. The antenna will be at least 45 feet from the ground in any
direction. I can believe EZNEC so far as the effects of ground on
impedance. but I am at a loss when it comes to considering the
patterns on the various bands. The ridge is about 200 feet from the
antenna.

This is for a club member who recently upgraded to General Class.

Since the ridge is close to the same height and south of the antenna,
I am guessing that the computed charts will be a good representation
of the northern half of the antenna. NVIS should not change much. The
terrain may work as a reflector for over the pole operation. I am
afraid the antenna will be of little use to the south.

I expect we will eventually need to do the best we can with an antenna
on the top of the ridge. When the snow melts I will try to climb the
ridge for a look-see. It will likely be difficult to install due the
dense trees.

Any comments, advice, suggestions etc. are appreciated!

The whole video sounded like a lot of verbal sleight of hand to me.
Its a shame techs and engineers are not secure enough in their
knowledge to recongnize BS when they hear it and report it as such.
"The Emperor's New Antenna".

KCBS, San Francisco, claims to be the direct lineal descendant of Charles Herrold's broadcasting, which dates from 1910. However, Herrold's early work involved broadcasting to amateurs, by his own admission. http://www.charlesherrold.org/KCBS.html, et al.

KCBS and KDKA, Pittsburgh, have been trading claims and counterclaims for decades. KDKA went on the air in November, 1920 and supporters of their claim of "First!" say KCBS doesn't date from the Herrold days, but rather from 1921, when they got their earliest commercial license, as KQW. I don't claim to be able to settle it here. Oy!

A year earlier PCGG in Holland started broadcasting on November 6, 1919
and is thought to be the first 'real' broadcast station.

On 15th June 1920 Marconi made their first broadcast to the public from
their works in Chelmsford, but it took until 1921 before there were
regular programmes.

Hello Jimmie,

It depends on the design.

In case of a classical transformer, it will be the same, except that the inductance can be divided by 4. Practically this means you can half the number of turns.

For example if the 200 Ohms side have 8 turns, you can reduce this to 4 and this will be the 50 Ohms side. As current increases (with same power), you may use thicker wire, or use two windings in parallel.

In case of a real transmission line transformer, you may need transmission lines with unpractical low characteristic impedance. Maybe you can provide some details about the type of balun you want to make.

Hello Jimmie,

It may not be magic (cheating), but it does not mean that this is the
only solution to get a wide band antenna with reasonable radiation
pattern.

Adding a second (even non-radiating) resonator to a quarter wave whip (or similar structure) does increase the useful bandwidth with a factor 2.5. I used this technique in some commercial UHF designs. "Electrically Small, Superdirective, and Superconducting Antennas" , R.C. Hansen, discusses the resonator technique also.

Adding a third resonator will give slightly more increase of useful bandwidth. Basically it uses the same design techniques as used in broad-banding amplifiers with LC sections. Looking to VSWR versus frequency, it looks like the put the resonator technique in a fractal appearance.

In very wide band applications (> 3:1), you can keep the VSWR within reasonable limits, but a whip-type radiating element may result in a clover radiation pattern. Flared thick structures give better radiation pattern.

I've never had any real problems even at 23cms. Certainly non even with
other feed techniques that I've tried.

> Also it defeats some of the purpose of a balun on a beam.

I agree that it wont necessarily prevent common mode currents on the
co-ax.

> The balun is to keep the current in the antenna balanced which the
> gamma match will not to.  This tends to skew the pattern of the
> antenna if the current is not balanced on the antenna elements.

I've not really noticed any problems with pattern skew, though I have no
doubt that it occurs.  I suspect that it would be more of a issue with
phased arrays.

OT.  Merry Christmas to all.  (*)

As did Marconi and several others, but they certainly could not be
described as a broadcast station, more like experimental demonstrations.

Again you must differentiate between sporadic demonstrations and the
setting up of a station with scheduled programming, which is what the
discussion is about.

I have just cut the prices on my 25th Anniversary edition of "Building a Super Station". The e-book download is now free, and the DVD and paper copies are $5 cheaper than before... Hopefully none of the reflectors object to this announcement since this removes any income I was getting from them, just one less form to file with income taxes after this year.

Get them at: http://stores.lulu.com/k1ttt

eham sucks
they "moderate" like a communist regime
I was kicked off for trying to resurrect a 1970s model linear that was
made for ham radio but was popular among the CBers of the time. I guess
to be a ham, you must purchase equipment from one of the eham sponsors?
```

eham is only trolled with a bunch of old dumb hams who have to have their great grand children or nurse maids turn the computer on for them each morning so they can go on a destructive rage with everybody young and new to radio.

HAHAHA Nice example!

Exactly why one should avoid eham!

The people who frequent there are simply too stupid to understand sarcasm
or anything complicated beyond what's on fox news. A disgrace to amateur
radio.

The operative words are "scheduled" and "public" in this context.

There were lots of one off things done before 1919.

This babbling moron has been posting his nonsense for years on the physics and physics.electromagnetic groups.

When I first read his posts years ago I thought his gibberish was because English wasn't his native language but soon came to realize that the issue isn't language, the issue is brain chemistry.

Recently he has moved to the amateur groups, I guess in hopes that the people here won't be as "harsh" as they are in the science groups.

You can give him facts and links all day long, but since he doesn't seem to have more than two synapses that fire properly, he will never understand any response and just continue to babble on.

So there are a few choices to answering his posts:

Don't

Remind him he is a drooling mental case

Respond with some facts that may be of interest to others when he accidently hits on something, such as the history of broadcasting, then remind him he is a drooling mental case

I had thought about the increased current and decided the best way to compensate for this may be to use a transformer designed for more power than I had palnned on using As I am only going to be running 100W PEP I figure using a design for 1000W would be more than sufficent. I had not considered the need for fewer turns. Is this important?

Do not be angry that you do not know if " did distance affect the
sidebands???? ". It is nothing wrong.
The effect is obvious in light of physics laws. Such obvious that fathers of
the radio did not write about this.
Young people can measure it if it is interesting for them.

distance itself does not affect sidebands.

frequency dependent dispersion in the ionosphere can affect sidebands
and the mark/space tones of rtty differently over short periods
causing differential fading and distortion.

Hello Jimmie,

When you take a transformer type 200 to 50 Ohms balun, the lower
```

frequency limit is determined by the inductance of the 200 Ohms winding (no load connected). This inductance is in parallel with the 200 Ohms source (or load).

When you short-circuit the 50 Ohms side, you will not measure 0 Ohms, but an inductance. This is the leakage inductance due to limited coupling between sec. and prim. winding.

When you use this same balun for a 50 to 12.5 Ohms circuit, the lower frequency limit will decrease. However the upper frequency limit will decrease also, as the leakage inductance is in series with the load.

You can imagine that 150nH (j28 Ohms at 30 MHz) in series with 50 Ohms load is acceptable in many situations, but this same 150nH in series with 12.5 Ohms load may give problems.

Regarding power handling
If you are using your balun with a load with bad VSWR (referenced to 12.5 Ohms), you have to derate power. If the transformer is in a voltage maximum, the core dissipation will increase due to higher flux in it. When the transformer is in a current maximum, wire dissipation will increase.

Best regards,

Wim
PA3DJS
www.tetech.nl
without abc, PM will reach me

One could also consider selective fading.

that's just another name for it... i threw in the big words because
i'm sure that mr.b will look them up out of context and find all sorts
of hilarious ways to recombine them.

I am sure that the all my questions will be explained with the ionosphere.
The first my question was on the frequency doubling.
But yours selective fading means for me "distance itself does  affect
sidebands". So you are very helpfull.

For me all names are clear.
Ampere discovered the electrons and give them name "current elements".
Maxwell used "electric particless". But you all admire Heaviside's fluid
(massles and incompressible). Do you see the difference?

Hardly.

At some frequencies the ionosphere is transparent, at some it is reflective,
at some it is absorptive.

And the iononsphere has little to nothing to do with ground wave propagation,
which predominates at AM broadcast frequencies.

But you haven't a clue what any of that means, do you?

> The first my question was on the frequency doubling.
> But yours selective fading means for me "distance itself does affect

Correct conclusion but for totally wrong reasons, much like noticing ice
cream is cold therefor the sky is blue.

> For me all names are clear.

Babble.

> Ampere discovered the electrons and give them name "current elements".

You are wrong as usual.

Richard Laming came up with the concept, the name was by George Johnstone
Stoney, the particle itself was identified by Sir John Joseph Thomson.

> Maxwell used "electric particless". But you all admire Heaviside's fluid

More mindless, word salad babble.

From http://en.wikipedia.org/wiki/History_of_radio

<begin quotes>
The question of the 'first' publicly-targeted licensed radio station in the U.S. has more than one answer and depends on semantics. Settlement of this 'first' question may hang largely upon what constitutes 'regular' programming.

It is commonly attributed to KDKA in Pittsburgh, Pennsylvania, which in October 1920 received its license and went on the air as the first US licensed commercial broadcasting station. (Their engineer Frank Conrad had been broadcasting from his own station since 1916.) Technically, KDKA was the first of several already-extant stations to receive a 'limited commercial' license.

On February 17, 1919, station 9XM at the University of Wisconsin in Madison broadcast human speech to the public at large. 9XM was first experimentally licensed in 1914, began regular Morse code transmissions in 1916, and its first music broadcast in 1917. Regularly scheduled broadcasts of voice and music began in January 1921. That station is still on the air today as WHA.

On August 20, 1920, at least two months before KDKA, E.W. Scripps's WBL (now WWJ) in Detroit started broadcasting.

There is the history noted above of Charles David Herrold's radio services (eventually KCBS) going back to 1909.
<end quotes>

So first define "broadcasting".

Mine is a station with a license with a target of the general public and a regular schedule.

Some of you play with the Moon. Are the sidebands the distance dependent?
The distance is huge and the ionosphere is transparent.

But note the start of the quote "<begin quotes>
The question of the 'first' publicly-targeted licensed radio station in
the **U.S.**"

The Dutch beat the US to it!! with regular scheluled programmes from
PCGG starting in November 1919 a year KDKA.

Whilst distance does not affect sidebands per se, it can affect which
sidebands are received, and hence the envelope of a recovered signal.

Consider a pulse train with a spectrum that extends to infinity; the
higher order sidebands when received by a distant station will be below

the noise floor and will not play a part in the recovered pulse train, so in a way distance has modified the spectrum of the received signal!!

Jeff

no, the sidebands are NOT distance dependent.

and no, the distance is not huge and the ionosphere is not
transparent.

Hello,

Does somebody have experience with ANSOF (www.antennasoftware.com.ar),
especially with planar circuits? Is this a NEC based package?

They say you can use a flat strip as basic element (like in the
"planar" commercial SW packages), though they speak of wire segments
in most other documents on their site. They also mention that you can
simulate wire segments in dielectric or magnetic media. This looks
nice for the relative low price.

Best regards,

Wim

How many times are you going to repeat this nonsense?

Sidebands and distance are not related.

You are a babbling idiot.

Thanks, would it be safe to assume that a transformer designed for 1
to 30 Mhz at 1KW could be used as I have discribed without
modification on 40M. I think the load side should be very close to
12.5. VSWR was 4.1:1 when measured with an Anritsu analyzer a few
weeks ago with no balun attatched. Unfortunately I no longer have
access to that piece of test equipment. The best I can presently
manage is a cheap VSWR meter. Its measurement also agrees with the 4:1
mismatch.

Hello Jimmie,

Very likely yes:

1 kW into 50 Ohms results in 4.5A. Your 100W into 12.5 Ohms results
in 2.9A. As your voltage is less, the core loss will also be less.
From a power standpoint of view, it is safe to use.

In addition, any phase of load VSWR=3D4 will not harm the balun at 100W
input, as the voltage will not exceed the voltage under 50 Ohms load
condition at 1 kW.

As it can be used up to 30 MHz, it is likely that the leakage
inductance at 7 MHz will not be a problem, in combination with a 12.5
Ohms load.

Best regards,

Wim

It is when the question is about the first regular broadcast station,
not about one off experiments.

>
>> Technically, KDKA was the first of several already-extant stations to receive
>> a 'limited commercial' license.
>
>
> OK, but the original claim wasn't "first limited commercial license;"
> it was "first experimental AM broadcast station."

No, it was about the first 'proper' broadcast station. ie not one-off
demonstrations or experiments. ie one with a published and regular
schedule, and a general audience waiting to listen.

Jeff

What is the effect of the inner conductor if I am using the shield only for one of the elements of an antenna? That is, the inner conductor is connected to nothing but the shield is driven.

Thanks,
John

Antenna current is on the outside of the outer conductor. The effect of the inner conductor is to add a bit of mechanical strength to the element. In fact, if you use RG-6 with a copper-clad steel inner conductor, that inner conductor will add considerably to the tensile strength of the element, and keep it from stretching so much if it's under tension. You can connect the inner conductor electrically to the outer at one or both ends and it won't have any effect (unless it extends significantly beyond the length of the outer conductor).

Cheers,
Tom

Hello Wim...

I haven't use it, but I can steer you to where you can get your questions answered.

Go to www.antennex.com , This site is devoted entirely to antennas and related items. Join the antenna discussion list (no charge) and post your question there.

If there is a group that is more aware of what is going on with antennas, I haven't found it. Everything from PhD professors to ex and current professional antenna designers to "just plain hams" (like me).

All the best

Bill Miller

If you transmit through it make sure you do it at night and have a video
camera on tripod ;-)

Hello Bill,

I made a free account for the "guest rooms". I checked several free
documents (lots of material from L. B. Cebik (W4RNL)). Nevertheless
nothing about "ansof". Maybe somebody with a non-free account can
check other parts of the website for ansof.

Best regards and thanks for the info,

Wim

Go out and ask 10 or 20 normal people what "broadcast radio" means.

Yes, the arguement is becoming one of semantics, but to most people "broadcast radio" means radio transmissions for the general public on a regular, scheduled basis.

documents (lots of material from L. B. Cebik (W4RNL)). Nevertheless
nothing about "ansof". Maybe somebody with a non-free account can
check other parts of the website for ansof.

Best regards and thanks for the info,

Wim
PA3DJS
www.tetech.nl

Hi Wim...

Sorry. I did not make myself clear. I do not believe there is any useful

information on this subject in the antenneX website, nor in Cebik's site.
(but there is a TON of other info there!)

From the antenneX website, subscribe to the antenna discussion email list
and post your question there. I'll be pretty surprised if you don't get
meaningful answers!

All the best,

Bill

be sure NOT to ask in here, since we are obviously not normal
people.... i'm more interested in how mr.B thinks sidebands are
distance dependent than what broadcast radio is.

their description doesn't mention NEC:

"The computer code is based on an Electric Field Integral Equation
(EFIE) expressed in the frequency domain. The current distribution on
metallic structures is computed by solving the EFIE using a full-wave
Method of Moments (MoM) formulation with conformal geometry
decomposition. This means that geometry details are modeled by using
conformal segments, which exactly follow the contour of the structure,
instead of the typical approximation with straight wire segments. "

lots of nice words, and plenty of pretty pictures on their site... but
i wonder how well verified it is.

Almost any height, being as the radials will need to be resonant
to work well. The only difference is the number of radials required
to equal a certain number ground mounted decreases as you
get higher off the ground.
But you have to think in terms of wavelength. What might be fairly
elevated on 10m, which almost be on the ground at 80m.
Say you compare to 120 radials on the ground, which is pretty
much a perfect ground within practical limits.

At 1/8 WL, you might need 60 radials to equal the 120 on the ground.
At 1/4 WL, you might need 8-10 radials to equal 120 on the ground.
At 1/2 WL, you can use 3-4 radials to equal 120 on the ground.
On 10m, 1/2 WL is only about 16 feet off the ground.
On 80m, 1/2 WL is about 120 feet off the ground.
In the past I've used a full size quarter wave ground plane on 40m at 36 ft, which is slightly over a 1/4 wave up.
I used four sloping radials. I came to the conclusion that the system was about equal to a ground mounted system with 60 radials.
Some have speculated that ground planes can be run very low to the ground with only a few radials, and still be nearly as efficient as a ground mount with 60-120 radials.
I'm not buying it. There is no free lunch in this regard. :/
If the vertical is elevated, but just barely, count on using almost as many radials as the ground mount for the same amount of ground loss. There will be a slight decrease in the number needed, but not by a large amount.
You will need 1/4 wave radials if elevated. They must be tuned. Ground mount, it doesn't matter. So you can't use short .1 WL radials if elevated. Only ground mount can you do that. Elevated, they need to be .25 WL, .75 WL, etc.. They have to be resonant, or otherwise they will be fairly useless.

My experience is as follows:

Hygain - Over the years I've owned a number of their products. Build
quality was consistently high. With overall fit, feel and finish what
one would expect from an old line firm.

ChushCraft - Much smaller sample base. Build quality was fairly high.
With overall fit, feel and finish acceptable, though a bit rough
around the edges. Good but not great.

>Are all the holes in the right place, are the tubes of the correct

Generally, yes. With the above comments taken in to consideration.

>More generally, will the things go together and stay together?
>

In my experience, yes. No failures over time. Survived high winds and
ice loading without catastrophic failure.

Hi,

does anybody has the exact dimensions of a Versatower 24 m.
I bought a seconhand tower, but I need the exact dimensions and weight for
the truckcompany who'll do the transport.
All plans, schematics are also welcome.

tnx on beforehand,

ON2XXX
Rudi

everything (and more) you always wanted to know about me :

Hello S=E9bastien,

I think it is a good thing to contact some people locally.

Besides support with the calculation for the inductors and capacitors,
small "construction errors" can degrade performance of a basically
good design significantly.

Be prepared to get many different answers to the same question!

Yesterday evening I experienced strong increase in mains supply
synchronized interference. After some elimination tests, the
"offender" was a new tiny switching plug-in adapter.

I had to use several ferrite cores to reduce the interference from
<3.3 MHz to >15 MHz to an acceptable level.   The volume and weight of
the ferrite cores I used exceeds that of the adapter.

Best regards,

Wim

About ferrite cores and tapped coils.... I was wondering about
something...

Imagine a tapped coil from a inductance value, let's say "i". what is the effect of progressively introducing a ferrite core (wand) inside the tapped coil? Reducing, or increasing "i"?

We were speaking about a Collins receiver. If I read well, it seems to use this kind of feature. Could be better for experimentation, no?

Sebastien.

p.s. I need to buy something to measure capacitance and inductance (RLC bridge...).

Here are thy unrestricted signal (upper diagram). It has the three peaks:
http://en.wikipedia.org/wiki/File:Passband_schematic3.png

So in an old radio the same station was in the three places (on the scale)
close to one another.
Am I right?

Nope, you haven't the slightest bit of understanding of what the term
"passband" means so your question is nonsense.

Hello S=E9bastien,

When you put in a ferrite bar of suitable material, the total
inductance will increase. The longer and thicker, the more will be the
increase of inductance. The actual increase depends on several factors
(length/diameter ratio of coil, and to a lesser extend, ferrite
magnetic permeability).

When I put 10*150mm^2 ferrite rods (from old vacuum tube AM/FM radios
I believe) into my simple single capacitor preselector, the lowest
frequency goes down from 3.4 MHz to 1.1 MHz. The 5 m wire outside

wire performs equal w.r.t. my small portable indoor loop on AM BC 1476, 1485 kHz (Spanish stations). Of course, loop positioned and oriented for best reception.

When you look into the technical documentation of ferrite producers/ vendors (Ferroxcube, Fairrite, Amidon, TDK, Epcos, Kitagawa, etc), they will show you a graph that relates inductance change ratio versus coil dimensions and ferrite permeability. Wrong choice of ferrite material will reduce Q-factor significantly.

The effect on a tapped coil in a circuit depends also on where you start pushing the bar into the coil, as the part of the coil closest to the ferrite bar changes inductance first.

Regarding LCR meter, There are some very nice kits around that measures small inductors and capacitors very well: http://electronics-diy.com/lc_meter.php gives an example.

Best regards,

Wim

Only three?  If the modulation is a complex signal (not just a single
sinusoid), you'll get (ideally) a carrier on a single frequency, and
upper and lower sidebands spanning a range of frequencies.  Any decent
spectrum analyzer will easily resolve these components.
Communications receivers with narrow bandwidth, sharp cutoff filters
can also resolve them, of course.

And only "in that time"?  You still can:  there are plenty of AM
stations broadcasting in the 0.5MHz to 30MHz range (and some outside
that).  But in 1915, it may well have been easier to analyze the
signal mathematically than with hardware.  The hardware may not have
been very common, but certainly the math identities required were
readily available, as was Fourier analysis.

What if both sidebands are NOT "saying the same thing"?  Then, for
instance, you can broadcast stereo in a way that receivers mixing the
two sidebands will still receive an acceptable mono signal.

Cheers,
Tom

Hi John,

It's common to calibrate measurements at the end of a piece of line with modern vector network analyzers. The analyzer does much of the work for you: you just put, in sequence, a short, and open and a precision load at the point you want calibrated, and the analyzer does the rest. Obviously loss in the line will reduce the accuracy of measurements: consider the case where the line has infinite attenuation; in that case the signal at the sending end of the line won't change at all for an infinite change in load at the other end of the line. The accuracy degrades monotonically as the line attenuation increases. Unless you're trying to get the absolute best accuracy you can, you probably don't need to worry about 0.8dB loss in the line (1.6dB round trip?). There's an HP ap note (or two or three?) about this. Maybe do a bit of Googling??

If you calibrate with open, short and load, you have the information you need to characterize the line's loss versus frequency and its delay (or phase shift). You don't need to also measure the line separately. You could view the calibration as having measured the line, in fact.

Cheers,
Tom

Many thanks, Tom. That's the answer I was hoping for. I appreciate your help.

Cheers,
John

Which, in this instance, has squat zilch to do with antennas.

Now my radio use FM. The one station is on the distance circle 1cm.
In 1915 was the same for AM?

>Only three? If the modulation is a complex signal (not just a single
sinusoid), you'll get (ideally) a carrier on a single frequency, and
upper and lower sidebands spanning a range of frequencies. Any decent
spectrum analyzer will easily resolve these components.

What was in 1915?

>Communications receivers with narrow bandwidth, sharp cutoff filters
can also resolve them, of course.

Have such Author of SSBHistory in 1915?

>And only "in that time"? You still can: there are plenty of AM
stations broadcasting in the 0.5MHz to 30MHz range (and some outside
that). But in 1915, it may well have been easier to analyze the
signal mathematically than with hardware. The hardware may not have
been very common, but certainly the math identities required were
readily available, as was Fourier analysis.

>What if both sidebands are NOT "saying the same thing"? Then, for
instance, you can broadcast stereo in a way that receivers mixing the
two sidebands will still receive an acceptable mono signal.

I am trying to find if that SSB from 1915 were the distance dependent.

FOR DISCUSSION...

RE: YouTube video on this subject at
 http://www.youtube.com/watch?v=QWd0nEXFnrE&feature=player_embedded

The comments in italics were posted on another website, which prompted
my five points that follow. Thought they might be of interest here.

It would be interesting to learn if the results and conclusions shown in the YouTube video have been confirmed from complete documentation by an independent test lab.

> but i have another idea that has come out.might be a game changer
> check this out. i have been researching this and it could be the
> breakthrough we need. a broad band antenna, no loading coil needed,
> double the eirp!

Observations from watching the YouTube video...

1. A 1/4-wave monopole was used in the test. A 1/4-wave monopole is self-resonant, so no loading coil was necessary. However it would be necessary for the electrically short monopoles permitted for unlicensed Part 15 AM, and would still be needed if the FCC changed 15.219(b) to allow a 30' "ground" conductor.

2. A 1/4-wave monopole driven against a perfectly conducting ground plane such as shown in this video has a peak system gain of about 5.15 dBi. The video shows a resonant gain for that monopole system without the sleeve as "1 dBi" referenced to the gain of a log periodic antenna.

However by definition the term dBi means decibels with respect to an isotropic radiator, and a log periodic antenna definitely is not an isotropic radiator. The gain units used in the video are therefore unconventional, and need further definition.

3. The relative field radiated by a conventional 1/4-wave vertical monopole driven against a perfectly conducting ground plane always is maximum in the horizontal plane. Such a system radiates virtually 100% of the matched power applied to its input terminals.

Therefore the peak gain of that antenna system at resonance cannot be improved by putting a sleeve of any kind on the monopole.

The sleeve may change the shape of the radiation pattern of the system without the sleeve, though, which could change the field intensity at the location of the receiving antenna used in the test. This could account for the ~3 dB improvement shown in their results when using the sleeve.

4. Nothing is shown in the video about the amount of matched power at the feedpoint with and without the sleeve. If that is not held constant then the test will be flawed.

5. The VSWR bandwidth of a monopole may be increased simply by using a larger cross-section conductor of "non-fractal" construction.

"Radio receivers generally include a tunable band-pass filter with a
passband that is wide enough to accommodate the bandwidth of the radio
signal transmitted by a single station."

For me a radio is a box with the knob to rotate.
Now at FM no brakes between stations. At AM are.

What was in 1915?

That statement is at best misleading, and in some cases incorrect.

In most receivers any *tunable* filter is MUCH MUCH wider than the
bandwidth required to accommodate the bandwidth of the signal transmitted.

The selectivity being produced by one or more *fixed* frequency filters
which are just wide enough to accommodate the bandwidth of the wanted
signal.

In 1915 there were no broadcast stations to speak of so your dial
would be just one large "brake" (sic).

----------------

Radio waves behaved the same in 1915 as they do now.

The distance to a given field intensity, for the same conditions,
is the same now as it was then.

Well sort of :-)

Before (and during) WWI, anything below 200 meters (over 1.5 mHz) was
considered too high in frequency to be useful.

Geoff.

Oh goody, you can cut and paste from a web site.
```

Yet you have no clue what the quote means or the implications of having ommited any mention of the IF stages of a receiver.

> For me a radio is a box with the knob to rotate.
> Now at FM no brakes between stations. At AM are.

Gibberish.

> What was in 1915?
> S*

The battleship HMS Formidable is sunk off Lyme Regis, Dorset, England, by a German U-Boat.

An earthquake (6.8 in Richter scale) in Avezzano, Italy, kills more than 29,000.

The 1915 locust plague breaks out in Palestine; it continues until October.

The theory of general relativity is formulated.

The first prototype tank is tested for the British Army for the first time.

Babbling gibberish.

SSB was a laboratory curiousity in 1915 and was little more than a set
of equations.

The modulation used has nothing directly to do with the distance a signal
is usefull. That is determined, at a given power and state of the the
ionosphere, mostly by signal to noise ratio which is influenced by the
bandwidth of the modulation method but not by the modulation method itself.

Electomagnetic propagate works the same today as it did in 1915 or even
30,000 BC if anyone had been around with a radio.

You are a babbling idiot.

I just watched the video one time and it diddn't sound like Chip to me not that it matters.
He is comparing to a log periodic as it is non frequency dependent.
When he placed a sleeve over the 1/4 wave it was fed I presume by capacitive coupling not that it really matters tho capacitive coupling does help with band extension and constant SWR. He first started with a circular sheet as a radiator over which he placed a second circular sheet that is perforated or mesh design.
A mesh design when fed acts like a closed circuit helical where the current applied takes little interest in the vertical connections so it to is non frequency dependant the same as the
log style antenna. The mesh current flow is a initial spurt of full current which then degrades to zero when it get back to the starting point after at least a single wavelength of travel, not a quarter wave. Ifg the frequency applied is of many wavelengths it will then display a near constant SWR over a extended frequency of which there have been many studies available to confirm. Again if their are enough wavelengths are present it gets to a equilibrium point of resonance which includes the overshoot of the applied current. I say resonant because he is not using fractional wavelength dimensions which are all floating dimensions where a period (full wave) is not. The overshoot of applied current increases as much as 5 times, so with the increase in current it is easily seen that as the current goes so does the radiation. One could turn around the whole experiment as one of a radiator inside a Faraday cage which is also used as proof of reciprocity with respect to radiation from a radiater that is in equilibrium. Thus it is exactly the same as what I have been proposing for many years which stems from the Gaussian extension to Maxwells equation.
I have just completed a similar antenna made as a flat solenoid without a plunger sometimes referred to as a Meander or pancake antenne.
It is close to 40 inches dia with a hieght of !/2"
My expectations is that when placed inside a faraday shield, an example of the Gauss extension it will have a resonance of at least 10 metres down to 160 metres with a SWR less than 3: 1 and an applied impedance of 50 ohms.
I was told that I had a patent on this if I paid publishing cost, acceptance fees and to follow maintanance fees which I declined due to the
high costs.
Best regards to all
Art Unwin

Tonight and yesterday night I played with my experimentation board
(loop...s on my shelves).

I have a 4 loops (square) web :
1 - 8 turns - 1.5 m /side
2 - 3 turns - 1.0m /side
3 - 1 turn - 0.8m /side
4 - 1 turn- 0.65m /side

Each one is inside the other one.

I used the second to be the matching one from the previous, the firts.
The third, to be the mathcing one of the second, etc.

The resonant one gets a variable air capacitor (I change it every time I need to go higher....).

Very interesting, indeed.

If I understand well, the loop gets the role of inductance and the capacitor the role of the capacitance... (Lapalisse...). Matching both gets the best result for a given frequency. I succeed in making apparent signals that I was not aware of... With this antenna I can tune in the frequency from 300 KHz to near 7300 KHz... Completely amazing. That's the first time I can exactly see (thanks to the waterfall information display) how it does increase, not only the signal, but what's more important, the signal/noise ratio. I understand now how this is very important...

What I can see, is that depending on the size of the loop and the frequency I am monitoring, the variable capacitor may or may not be very difficult to use, and the bandwidth lack of noise, narrow or wide...
Interesting to see that it is possible to increase the signal without increasing a lot the signal/noise ratio (better than nothing :). But you can't play when the signal is too weak.... :)

I am quite happy. It does not tell anything about the antenna efficiency, but it helps me understand how it works. I get somebody in my family who is a physics teacher... I need to ask her information about "RLC oscillators for newbies" to be able to put some rational things upon my experimentations :)

To do next :
- Try to carry out the tiny preselector from Wim (need to find some coper wire... And need to try to recover some old radio parts to play with.... (get some ferrite rods, low value variable capacitors, etc.)
- Try to get some time, and some place, to play with long wires, dipoles and their related matching systems...

Sebastien.

Look at the damped waves: http://en.wikipedia.org/wiki/Damped_wave

The damped waves pulses are simillar to AM (amplitude of oscillation
decreases/increases with time).

The decreasing/increasing may be sharp or gently.

The old damped waves  " transmissions have a wide bandwidth".

Was the bandwith the distance dependent?

"Well, it's like this. The story starts in 1915, when mankind discovered sidebands. Now possessing this superior understanding of the AM signal, radio scientists began to understand the implications of their discovery. Soon afterwards, our old friends at Bell Labs, who have discovered practically everything, developed a method for removing one of the sidebands of an AM signal but retaining all the essential modulation components. As an expert of that day supposedly said, "both sidebands are saying the same thing" (Goodman, 1948). " From:
http://www.hamradiomarket.com/articles/SSBHistory.htm

If in 1915 were no broadcast stations to speak tell us what was with the first station to speak and when it start transmitting.

The first AM Broadcast station (as opposed to amateur or military ) was
in about 1919.

Damped waves bear little or no similarity to AM, they are essentially
pulses with a very different spectral content.

Being pulses the spectral content is wide, tending to infinite, and yes
I suppose that the spectrum received by a distant station will vary
depending on distance; the lower level spectral lines that are spaced a
long way from the fundamental will be lost below the noise as you get
further away or the signal gets weaker due to propagation changes. The
more side-bands that you loose the slower will be the rise and fall time
of the received pulse.

AM is very different the spectrum is much more contained and only 1
side-band is required to replicate the waned signal.

Hello, all. With the wealth of info available on eham.net I'm beginning
to wonder for amateur radio purposes if it's still worth the time to
stay on unmoderated, spam-laden usenet newsgroups. Your time and
comment is appreciated. Sincerely, and 73s from N4GGO,

A decent news client and news provider and well-populated filter and
killfiles makes reading any newsgroup a much nicer experience.

There were no broadcasting stations of any kind in 1915.

The first station that could even remotely be called a broadcasting station
was in 1916 and it broadcasted weather reports in morse code.

The first experimental AM broadcast stations started in 1919 and regular AM
broadcasting started in 1920 when all the spark gap morse transmitters
were shut down.

Hello,
I am in the process of building a 4 element 2m yagi, centred in 146 Mhz and will be utilising a folded dipole for the driven element.

I came across a commercial folded dipole, fed with coax that had been threaded inside of the driven element. the coax exits through a hole in the centre of the dipole opposite the feed point.
The coax is connected directly to the ends of the dipole, but on closer inspection it is different coax on the feed side to the coax tail, so obviously it is a matching transformer.

Would this be a type of a trombone balun? Assuming it is, then there would be a 1/4 w/l of 75 ohm coax connected to the 50 ohm tail.

Are my assumptions correct?

Has anyone had any experience with this type of matching transformer? I like the look of it as it is certainly tidier that an external 4:1 coax balun.
73
John Vk2KC

More or less :-)

I've tended to prefer a gamma match... its far more flexible in terms
of matching and does the balanced to unbalanced conversion as well.

A T match with a 1/2 wave phasing line between the two sides of the T
is what Telrex used to use, very simple to build and rugged.

Several years ago I pulled apart a commercial 160MHz yagi antenna as you describe. It had a very thick folded dipole driven element. The 50 ohm coax tail was feed in at the boom through the inner of one side of the folded dipole & was connected to quarter wave length of coax (120/123 ohm from memory) & the other end was connected to the folded dipole feed point (centre to one side & earth to other).

I pulled it apart to have a look because I was interested in how the very wide bandwidth specification of the antenna was achieved (specification covered whole upper VHF commercial band).

Essentially just a quarter wave length matching section of coax from 50 to 300 ohms.& very thick driven element

Best wishes for Christmas to all on the group.

Might find this Christmas YouTube of interest

I want to contruct a 4:1 BalUn but instead of stepping the impedance
up from 50 to 200 I want to step it down from 50 to 12.5. Is there any
difference in design between the two.

Jimmie

The gamma match does not seem to be thought of as working very well at vhf
and above. Also it defeats some of the purpose of a balun on a beam. The
balun is to keep the current in the antenna balanced which the gamma match
will not to. This tends to skew the pattern of the antenna if the current
is not ballanced on the antenna elements.

well, maybe you should have... after all, some of us do use things
written by those bodies.  some of us help write and test those
standards.  and it sure would be nice if we could refer to a standard
way of describing antenna performance.

If I were you I would be more concerned why so many of you posts appear
twice.

If this is so important to you, I am sure you will be researching all
the electromagnetics textbooks, antenna texbooks, industry and trade
publications, the ARRL, the RSGB, manufacturers, and everyone else with
any interest in antennas to determine the "correct" usage and definition
of the terms in question, and submitting a draft proposal to the IEEE.

nope, i don't care that much, but you sure seem to be insisting there
is a correct usage when obviously it hasn't ever been really agreed
upon by the right people.  so you are the one who should be trying to
get all the worlds authors to agree to define it the same way and get
it into all the text books where its been missing all these years.

Hi S�bastien,

I'm sure there is - somewhere. GoogleEarth would be an elaborate tool
to accomplish this.

>I found the "Receiving Antenna Handbook" quite cheap, but the "Loop
>Antenna Handbook" is still expensive. Between $60 to $257... I will try
>the cheapest.

Myself, I would not advise spending more than $20. Professional
antenna books barely give more than one section of the first chapter
to its discussion.

>
>Do you calculate that in constant dollar from the 50's? :)

Today's cost matched with the price of equivalent performance from an
available vendor.

>I can imagine the teaching class. Everybody with a Collin's in front of
>him/her... A one year project to restore completely one of this legendary
>radio. I would like that!

There were two to a radio. 40 to 30 hours learning the schematic
theory of operation; and troubleshooting and tuning procedures and 30
to 40 hours in front of the radio. The class was 2 weeks long.
Complete restore unnessecary, of course, as the last class had fixed
any problem. No, we had a data bank of known problems, known
solutions, and the time to debug them averaged over at least 100

students for each problem.

>With a good DSP outside (Audio DSP only), can beat every other ones?

Good for filtering, probably tighter than the mechanical filters
(theoretically), but there are many, many other considerations.

>It seems not easy to get one, especially in Europe...

That seems like a very real impediment. And with it weighing in at 85
pounds (40 kilograms), the cost to deliver would add considerably.

So if the IEEE doesn't mention it in some standard everyone else is wrong?

Since there are electromagnetics textbooks, antenna texbooks, ARRL books
and web sites that all say the same thing, it appears there is some
agreement out there in the real world.

As for what's missing in some selection of books, I'm quite sure that if
you do a comparison of every book on a given subject there will be
differences in the topics covered.

That would be babble about why making blanket statements without adequate research is not an effective decision. That is what you did isn't it? Does everything that questions your highly self-valued input become babble?

On Tue, 14 Dec 2010 16:54:40 -0000, jimp@specsol.spam.sux.com wrote:

>The term "antenna efficiency" has a unique and unambigous definition and
>can be found in any textbook on electromagnetics.

Speaking of babble, which parts of that statement have been shown to be true? The balance can truly be considered babble.

>> The post concerning "a unique and unambigous definition" which "can be
>> found in any textbook on electromagnetics" and subsequent
>> back-pedaling appears to fit that model. Your "So what?" provides the
>> meh.
>
>Yeah, the "back-pedaling" which consisted of changing "any textbook" to
>"many textbooks".
>

And let us not overlook how the "a unique and unambigous definition" became "the term is in common use". Adding conditionals to what was a statement of absolute certainty does not make the original assertion any less flawed. That's just woulda, coulda, shoulda revisionism, an attempt to change the question to make it better fit the known answer. What makes that path better than the simple admission of having made a mistake?

>And nowhere did I reference any standard, IEEE, ISO, or any other standards
>body.
>

Yep you made no reference to any standards except for the ones you made up. Now you're making excuses for failing to refer to any other standards before making assertions which turned out to be wrong.. Alibi all you wish but the flaws in your assertion of "a unique and unambigous definition" which "can be found in any textbook on electromagnetics" have been exposed.

><snip remaining long winded babble>

What you call long-winded babble was

- quote -

You took what may be a perfectly valid general rule, tried to convert it to an absolute certainty, and failed. That's so what.

- end quote -

How could those two sentences be made to contain less babble and be made more concise?

Denigrate the messenger all you wish but that will not change the fact your blanket statement was nothing more than an uneducated, unfounded opinion. Please note I refer to the opinion as being uneducated and unfounded not the individual. Whatever your education, skills and experience are, the aggregate is unrelated to the fact you come across in the context of a small person who is rather full of himself. Let me just pat you on the head and say 'you win, you're right because you say so'.

That is an option, as they are frequently used in VHF/UHF systems. The
varactor is a non-linear device, so you may get intermodulation in a
large signal environment. You may use the varactor as fine tuning in
combination with fixed capacitors.

Did you try the balcony fence or other large metallic structure as
floating ground (counterpoise)?

I don't know the name for it, it is just a parallel resonant LC
circuit where the input and output goes via an inductive tap. Moving
the tap changes the coupling between the source/load and the resonant
circuit, hance changing the loaded Q-factor.

I fully agree on your statement, as these wide band receivers have
poor large signal performance, and don't have waterfall display....
However sometimes portability is of importance and then they can be
useful.

Hello,

Not too sharp with antenna and noise theory, so please bear with me a bit.

If I have a run of coax from a Balun right at my outside receiving only antenna (well grounded at that point) right to my receiver, is it still possible to have common-mode noise induced into the coax ?

Say from a PC, Modem, Router near the receiver.

Wouldn't the coax shied prevent this ?
If not, why not ?

Can't picture how an emi source field would/could "get-thru" the coax shield to the inner conductor.

Thanks,
Bob

It doesn't have to. The inner shield and outer shield are shorted together at the chassis. If noise exists on the chassis, i.e. the chassis is not really "ground", the result is differential noise on an unbalanced input. Essentially the same thing happens when SWR meter readings are affected by common-mode signals during transmit or when an unbalanced antenna analyzer is connected to balanced feedline without a choke. A good choke on the coax near the chassis often reduces the magnitude of the problem in all of the above cases.

On Dec 15, 2:17=A0pm, S=E9bastien MEDARD <t...@tut.com> wrote:

>
> Do you tune it, or not? Is there a small loop inside or not?

Yes for both. The cap is down at the bottom corner, and
I use a separate coupling loop because I'm feeding coax
to the radio. The 42 inch per side loop uses 5 turns on
the main loop. The coupling loop is on the inside, and
maybe 36 or so inches out from center.
Sounds like you are in good shape for caps.
That 500-500 would be good. I'd put a small mini switch
between the two gangs to be able to cut or add the
second gang. That's what I do on mine anyway.
I solder the switches right to the tabs on the cap.
I also have a handful of fixed caps to add if I want to
drop further down into longwave. I don't use them that
often so I just clip them on if needed.
I think my 16 inch round loop has about 12 turns if

I remember right.. It also uses a inner coupling loop.
For me, those loops are mainly for AM-BC, but I do
wander down and listen to the air beacons from time
to time. And the big one covers 160 meters, so I
use it for that sometimes.

Hi,

Thanks for help; appreciate it.

I wasn't too clear.

By the "inner shield," I mean the signal carrying innermost (solid)
conductor of the coax.

Guess I am wondering how can emi noise get thru the outer shield and to
the signal carrying conductor. Unless, of course, it's a really poor
outer and leaky outer shield.

Regards, and thanks again,
Bob

OK.

Not at this time. This is planned.

>> > If you use a tapped coil preselector (like the one in my link),

>
> It is the simple thing I referenced earlier
> www.tetech.nl/divers/SimplePreselector2.jpg

Sorry... Yes, your design seems quite simple. But as a beginer, I think i
get some problems to understand how things are connected to the variable
capacitor, I mean I think the way the variable capacitor works is missing
in my information pool...

Based on your photo let say we get :
On the upper side : two connectors
On the lower side : two other connectors

But the upper side connectors are connected to the lower side connectors... via the capacitor itself. Am I right?

The tap coil preselectors seem quite easy to carry out. You use different connectors on the tap to select the band you want to use.

You get a switch on the upper side that seems to avoid using one gang of the capacitor... But I cannot see of it is connected to the ground or not.

The air capacitor ground is connected to the ground.
On the right side, the tap coil preselectors are connected to the ground too.
There is a tiny capacitor that connects one gang to the ground again.

The central board should be used to avoid both tapped coil preselectors to get an inductive action on the other?

Is this correct? Would it be possible to get the schematic so that I could try to carry it out?

How did you compute the place to put the connectors (number of turns) for the tapped coil connectors?

>> > and have

How do you use it? Quite a blind test, no?

I have a big QRM (well, I don't know what it is) at 1500 MHz and other smaller ones elsewhere that I cannot switch off :))

Sebastien.

i think i have figured that out... if i post to the group it takes me
right back to reading messages... and then if i do a refresh it must
try to do the same post it just did since that is how it got to the
current page.  i'll try to remember to go back to the message list
first which seems to avoid that problem.

I should try to see if there are any OM near the place I live. Could be
interesting to see those old boxes.

Well, many thanks for the basic information you gave me.

Now, I need to use it.

Sébastien.

Hello S=E9bastien,

This: http://www.tetech.nl/divers/Simple_HF_Preselector1.png will help you. It shows the basic idea of a simple single variable capacitor preselector.

You can use one coil and put two selectors on it, but with two seperate coils the attenuation for out-of-band signals is much better. This is because the individual turns of each coil have low mutual coupling (they don't act as a transformer).   As I have sufficient antenna noise, the selectors (in my case clips) are mostly on the lowest position (I don't need matching to get more signal and noise).

For AM BC operation you need more turns (w.r.t. the coils on the photo).

Wim
PA3DJS
www.tetech.nl
without abc, PM will reach me in most cases.

One key point here is that the coaxial cable shield is grounded at two points, at the receiver and at the antenna. You might have what is known as a ground-loop. The best thing to do is to ground the receiver, the computer, the modem, and the router with leads as short as possible, AND TO THE SAME GROUND POINT. Since you have a balanced to unbalanced conversion (Balun) at the antenna, there is no need to ground the coax shield at this point.

Years ago, I had three grounds in my ham shack: the power line ground at the service entrance to the house, the tower ground where I had mounted a rotary coax relay, and a copper cold water pipe running beneath the shack which connected to the buried galvanized water pipe running from the street to the house. I measured from 3 to 15 volts AC between the three grounds. When connecting them together, I measured as much as an amp of current flowing. I bonded everything together at the water pipe and used this as the single point ground to which everything else was grounded.

I agree with Cecil that the noise is probably common mode noise. But the quality of the coax certainly does affect how much signal leaks in or out of a coaxial cable. I haven't bought Radio Shack coax in years, but it used to be very poorly shielded. The braid shield looked more like window screen than it did a solid sheath. This is the reason most CATV providers use flexible coax with two shields: a foil or metalized plastic shield covered by the braid shield. Special coaxial cables with high leakage are often used in long tunnels to provide FM reception in the tunnel.

I'm really short of space for antennas, but I think I might be able to
get away with one of the small HF beams I see advertised if it could be
mounted on a roof-top tripod. Dimensionally, I think a conventional
3-element beam would fit, but I don't think a roof-top mount would be
adequate.

Are any of these even worth considering?

I came by it while demolishing a motel. A roll of green rope was in storage there. Dont know what it would cost if I had to buy it. Hemp rope is cheap if you can find some that is raw and not impregnated with oil it should take resin pretty good. Fortunately the kind with no oil is the cheapest. Ive experimented with rope made of paper, soaking it with resin also made some rods I believe could be used for your pupose. I never used them for anything but they I had a couple of 2m lengths outside for 5 or 6 years before disposing of them. I was surprised at how well they held up. Im sure they would have done even better if they had been painted.. Not sure of the cost but it should be very inexpensive. Cost of the resin would be the biggest factor.

Common mode RF signals cannot exist on the inner conductor of an
ideal coax feedline and is forced to the outside of the braid by the
laws of physics. The coax has to be less than ideal for common mode to
exist on the inner conductor. But common mode signals don't have to
make it to the coax inner conductor to cause noise problems in a
single-ended unbalanced receiver circuit. A differential amplifier is
often used in control circuits to minimize common-mode problems. A
link-coupled transformer will accomplish much the same function for
amateur circuits.

Lets try the simplest expalnation first. If you are familar with RF
current flowing on the outdside of a coax cable during transmit(often
discussed here) it is the same thing but in reverse.

Jimmie

OK.

> For AM BC operation you need more turns (w.r.t. the coils on the photo).

As I want to use it from 0.5 to 30MHz, what would be size of both coils?
How many turns? What diameter? What would be the value of the C1
capacitor? A lot of questions....

Thanks again.

Sebastien.

> in good shape for caps. That 500-500 would be good.

Great.

> I'd put a small mini

> switch between the two gangs to be able to cut or add the second gang.

Definitively a good idea.

> That's what I do on mine anyway. I solder the switches right to the tabs
> on the cap.

Good advice.

> I also have a handful of fixed caps to add if I want to drop
> further down into longwave. I don't use them that often so I just clip
> them on if needed.

Planned.

The thing that can be done is to use the same base board on the different
loops to be used. Tell me your thoughts.... I was planning to put
everything on a wood board...

> I think my 16 inch round loop has about 12 turns if I
> remember right.. It also uses a inner coupling loop. For me, those loops
> are mainly for AM-BC,

It seems the size of the loop (I didn't play with loop software yet) is
not critical, but is it possible to say that the lower band you want to
listen, the taller loop you should use?

> but I do wander down and listen to the air beacons

> that sometimes.

Well... Sorry for the newbie question.... But what do you mean by beacons?

Sebastien.

Hi Sebastien,

Reg Edward's software, that you already have access to, will answer
that far faster than asking here.  Reason for that is because of all
the variables that come into play.  You can judge for yourself when
you enter them into the program and observe what results are returned.

Hello,

Wish to check out my receiver/antenna on USB signals.

Having a bit of trouble latching on to any.

Are there any USB stations/transmitters that are more or less always
transmitting, and have a reasonably strong signal ?
Live outside of Boston.

For LSB ?

Thanks, and Happy Holidays,
Bob

for usb try between 14150 and 14350 during the day
for lsb try between 7125 and 7300 just about any time, but especially
at night.

I use a 9ft Glen Martin with an A-4S.   Its not a DX Killer but you will work them.

20-25ft up has it limitations on some DX but its doable.

Hi Bob,

Tune into international shortwave broadcasts. Even though they are AM, the have both upper and lower sidebands (yes, I know, didactic). Still and all, it will give you some feel for tuning a signal in. For some receivers that can split a band with narrow IF filtering, this is a good way to DX weak AM signals.

Try WWV at 10 MHz (or any of the other frequecies they transmit on - multiples of 5 MHz). It is AM so both sidebands are present.

Aviation HF stations are USB. For example, Gander and New York VOLMET
stations on 3485, 6604, 10051, and 13270 MHz

Hello,

Trying to find a source who actually has in stock a coax patch cable.
Looking for a 6 inch length, SMA M on one end, and a BNC M on the other.

Would be using to provide some flexibility between components.

Coax type probably isn't all that important, as it's a receiving only
application up to 50 MHz, and such a short length.

But a "small" cable O.D. dia would be, to provide some flexibility.

Lots and lots of sources on the web, looked at many, but none seem to
stock anything like this.
As the quantity is small, three pieces perhaps, having someone make a
custom cable doesn't make sense.

Is there a consensus perhaps as to which outfits might have something
like this in stock, and specialize in small quantity "stuff" like this,
that I might have missed ?

Thanks,
B.

Hello,

Do you have some background in electronics and/or AC circuits (concept
of reactance, impedance, resonance, etc)?

Wim

i don't see one that short, but this place does custom make them
pretty quick:
http://www.aaarfproducts.com/SMACABLEASSEMBLIES.aspx
maybe just buy a 12" sma-sma and add your own bnc's to get 2 cables.

Pasternack Enterprises has BNC-M to SMA-M adapters, and can make cables with these end connectors using both RG-58C/U and RG-174. Cost will be in the $25 to $35 range. I have done business with them before and been very satisfied.

Go to Ebay, do a search on SMA male and take your pick!

I have bought good quality patch cables for less than $us8, exactly like the
one you are looking for.

I should.... But I was better in chemistry :) I should have studied RLC circuits but at this time it was boring... If I had some interest in shortwave listening, I would have been a better student in physics :)

But I should be able to understand :) I think I am going to see if there is any radio club near the place I live. Because I have a lot of questions and English is, as you understood it, not my main spoken language :)

Seb.

Hi -

My frequency of interest is about 434 MHz. I have the following equipment:

HP 8405A vector voltmeter
HP Accessory kit for the above
HP App note AN77-3 (compliments of Wes Stewart)
Fluke 6061A signal generator
Mini-Circuits 40-1000 MHz dual directional coupler.

I'm not sure the info above is really required for this question, but I thought it couldn't hurt.

The question is: I use about an 8-foot piece of coax to go from the output of the directional coupler to the antenna so as to reduce my body and instrument influence. When I follow AN77-3, I do so at the antenna end of the coax. That is, I set up the 8405A with a short at the end of the coax. I figure the coax is only about .8 dB of loss. Is this a valid way of doing the measurement, or must I set up the 8405 with a short on the output of the coupler and characterize the coax and then calculate the answer?

Thanks,
John

Hi Bert:

I don't have any empirical evidence one way or the other. However,
knowing a bit about manufacturing... I think that I can reliably say

that any antenna design prior to the acquisition would in all likelihood be unchanged from the original design parameters.

The other side of that thinking... a new design, post acquisition would be an unknown.

Just my two cents...

Merry Christmas

Tom G, Sr.

I agree that they're unlikely to have changed the design on any of the
existing products.

I'm wondering about the quality of the manufactured parts.

Are all the holes in the right place, are the tubes of the correct
length, are all the soldered connections actually soldered, etc?

More generally, will the things go together and stay together?

Hi, Any know anything about Marine ATUs?

Trying to get my auto-tuner working again but no info how to get power to it.

This one is by Marine Technology International Limited and is dated 1996. It has the usual fixed 2182 tune switch for coastguard.

Any experience welcome! Thank you indeed!

Dave

I hae bought several things from MFJ and think of it as an almost done kit.
Have had to go and resolder a few connections, callibrate a wattmeter,
tighten many screws.

Hello,
a big name in the antenna manufacturer say in the brochure of their vertical
antenna: "minimum recommended radial requirements: at ground level, 8
radials of 0,1 wl each calculating the lowest operational frequency. Above
ground, 2 radial cut for the specific frequency for each band of operation."

Assuming a operational frequency e.g. 7 MHz, at what height from the ground
one can consider the antenna mounted "above ground" ??

TIA and 73,

A superior alternative solution from the 1940s (edited to length):

Work has been proceeding in order to bring perfection to the crudely conceived idea that would not only supply inverse reactive current for use in unilateral phase detractors, but would also be capable of automatically synchronizing cardinal grammeters.

The main winding is of the normal lotus-o-delta type placed in panendermic semi-boloid slots in the stator, every seventh conductor being connected by a nonreversible trem'e pipe to the differential girdlespring on the 'up' end of the grammeters.

Forty-one manestically spaced grouting brushes were arranged to feed into the rotor slipstream a mixture of
high S-value phenylhydrobenzamine
and
5% reminative tetryliodohexamine.

Both of these liquids have specific pericosities given by
P = 2.5(C � n^6) - 7
where
n is the diathetical evolute of retrograde temperature phase

disposition
and
C is Cholmondeley's annular grillage coefficient.

Initially, n was measured with the aid of a metapolar refractive pilfrometer ... but up to the present date nothing has been found to equal the transcendental hopper dadoscope. ... It has been successfully used for operating nofer trunnions. In addition, whenever a barescent skor motion is required, it may be employed in conjunction with a drawn reciprocating dingle arm to reduce sinusoidal depleneration.

lets see, you remove the resistance which is the 'real' part of the
impedance, which gives you the imaginary reactance part as noted by
the 'j' above, and you think its real... probably just as real as your

pancake antenna in its faraday cage. you never have explained how my
ferromagnetic antenna works without your magical diamagnetic
levitating neutrinos.

Silly
Radiation is a vector product of two vectors, gravity and rotation.
The resultant vector cannot be at the same angle as the constituent
vectors there it must be tipped.
